Abstract. The Linked Brazilian Amazon Rainforest Data contains observations about deforestation of rainforests and related things such as rivers, road networks, population, amount of cattle, and market prices of agricultural products. The Linked Data approach offers thus to combine ecological, economical and social dimensions together. Our aim has been to 1) dramatically shorten the time needed to collect information for a research setting concerning the Brazilian Amazon, and 2) via the linkage between datasets enable novel types of transdisciplinary research for the scientific community.

Keywords: Brazilian Amazon, Linked Open Data, Deforestation, Spatio-temporal Datasets

1. Introduction

Open Science needs Open Data to maximize the transparency, reproducibility and reuse of scientific efforts. An example of a high demand for data is the research about climate change, for example about the role of deforestation in it.

Deforestation and its related phenomena such as market prices of agricultural products form together a complex system. There is an urgent need to share and publish research data about it, as it would enable other researchers to interconnect their data to the published ones. The benefit is that these explicit interconnections allow for the analysis of all of the resulting linked data in a transdisciplinary manner. Thus the whole complex socio-economic and environmental system could be modelled and not just subsets of it.

In this paper our contribution is to describe how large amounts of remote sensing observation data about the Brazilian Amazon Rainforest has been published as Linked Spatiotemporal Data. The data covers the whole Brazilian Amazon Rainforest. Moreover, we show how this data can be further accessed and analyzed using R statistical computing environment by openly available methods via a tutorial. We argue that this is a contribution towards Linked Science[3,2], where not just publications, but data, methods, tools, and other scientific assets are interconnected and shared online. The work is a continuation of our earlier work[4], but with substantial additions to the published dataset.

2. Linked Brazilian Amazon Rainforest Data

2.1. Linking a Diverse Variety of Data Together

Governments maintain a diverse amount of different registers—e.g. about population, export, employment, river structures, etc.—for decision making. These data are also very valuable in statistical analysis for finding correlations between different phenomena. Open and broad access in a uniform way to such data cases and enables scientific research.
Our aim is to create a unique dataset which we call the Linked Brazilian Amazon Rainforest Data (LBARD). The goal is to enhance research about deforestation. Motivation is that while the Brazilian government and increasingly also other authorities provides public access to data as spreadsheets, the linkage between these data is missing. Thus this creates challenges to conduct e.g. time-series or spatial analysis.

2.2. Study Area

The study area is the Brazilian Amazon rainforest, which covers an area of more than 5 million square kilometers. Data representing deforestation, land uses—pasture, temporary and permanent agriculture—and natural and social factors of change were aggregated to grid cells of 25 km x 25 km, counting a total of 8580 cells. For each cell of the resulting grid, there are 38 natural and social factors available, grouped into eight categories—land use, demography, environmental, accessibility to markets, technology, public policy, market pressure and agrarian structure. Each of the variable was described similarly as below the variable DEFOR_2004 (which is used to describe the percentage of new deforestation in 2004 for each grid cell).

2.3. Describing Deforestation and Land Uses

We made use of the Landsat TM-based 1997-2007 deforestation maps produced under the Amazon-monitoring program of the Brazilian National Institute for Space Research (INPE) in year 2010. The percentages of accumulated deforestation in different years were computed for each grid cell. The accumulated deforestation in 1997 and 2007 was decomposed into the main agricultural uses—pasture, temporary and permanent agriculture. Economical data provided by Brazil’s Informa Economics FNP, number of conservation units provided by the Brazilian Ministry of Environment (MMA), and distances to road structures from data by the Instituto Brasileiro de Geografia e Estatística (IBGE) were aggregated to the grid level in a similar manner.

The excerpt below shows an example grid cell with accumulated and yearly deforestation values.

2.4. Processing and Describing Data from Data Portals

In order to process and describe other statistical data such as census data, we developed an application capable of downloading from IBGE data portal, and transforming spreadsheets into Linked Data. The process made use of the Open Linked Amazon (OLA) vocabulary tailored for this purpose, and a number of established vocabularies. Open Linked Amazon vocabulary assembles classes and properties describing specific measuring units and variables used for the Brazilian government for publishing records. The time series are built on observations of a specific variable in a certain time period. The OLA Vocabulary was also in use to describe data for the project Dreieck der Nachhaltigkeit (Triangle of Sustainability), which participated the German science competition “Wissenschaft im Dialog 2012”.

Below is an example excerpt from the data.

```

As a result of the dataset contains the following data:

**Amount of Deforestation** The observed deforestation aggregated to grid cells (see [1] for details of how the aggregation was done).

**Cattle** The total number of heads of cattle grouped by municipality.

**Legal Amazon Grid** This grid covers the whole Legal Amazon area divided in 8480 cells with the size of 25km x 25km.

**Municipalities and Federal States** A complete compound of Brazilian Federal States which belong to the Legal Amazon area and their municipalities, together with their geographical location and covered area.

**Permanent Crops** Crops of produced from specific plants which last for many seasons classified by hectares of planted and harvested area, thousand reais, metric tons and kg/hectare. The permanent crops are linked to an observation and additionally its plants are linked to their respectively entries in DBPedia.

**Population per municipality** Census 2000 and 2010, and population projections from 2001 to 2009.

**Temporary Crops** Crops of produced from specific plants which last for less than one year classified by hectares of planted and harvested area, thousand reais, metric tons and kg/hectare. The temporary crops are linked to an observation and additionally its plants are linked to their respectively entries in DBPedia.

**Rivers** Rivers which geographically overlap a Legal Amazon Grid cell.

**River Basins** River basins which geographically overlap a Legal Amazon Grid cell.

The basic information of the dataset is as follows:

- Name: Linked Brazilian Amazon Rainforest Data (LBARD)
- Version date: 2012-05-16
- Version number: 2.0
- Licensing: Creative Commons Attribution-NonCommercial-ShareAlike 3.0 Unported License.

2.6. Metrics and statistics

Table 1 reports the variety and amounts of data that was linked together, to external datasets, and which vocabularies were in use for different types of data. The column total external links show the amount of data linked to DBPedia: Brazilian municipalities, data sources and permanent and temporary crops (cultivated grains). The choice for linking the Amazon Rainforest dataset to DBPedia was based on the huge amount of its incoming links from other datasets and the absence of more dedicated Linked Open Data data source for the Rainforest dataset purposes.

3. Example Use Case: Accessing the Data from R

One crucial aspect is how to access and analyse data, and especially how to get only that part of data which is of interest for a given research question. Linked Data solves the access part, and SPARQL allows to query only a subset of the data. For statistical computing there are tools like R⁹, and a separate package¹⁰ for it supports querying Linked Data.

As an example use case we provide an online tutorial¹¹ to explore the data from R and plot it on maps. The aim here is support bridging of the two communities, those of statistical computing and the semantic web.

4. Shortcomings and Future Work

The original plan was to use The Statistical Core Vocabulary (SCOVO)¹² for describing the data, but we changed the plan since SCOVO got deprecated. However, we are currently exploring the possibility of using RDF Data Cube vocabulary¹³, but its W3C status as draft implies risk on using it, making more sense to use the OLA vocabulary for later linking or migration when RDF Data Cube becomes a W3C recommendation.

However, we showed in this paper that we provide 1) an extensive amount of external linkage, and also 2) make use common vocabularies, and that 3) the published dataset as such can be used for extensive analysis of related phenomena concerning the Brazilian Amazon Rainforest. In the future work we plan to extend the dataset further by including diverse open data concerning ecological, economical and social aspects related to rainforests. Moreover, we are currently developing a set of applications that make use of the data. We hope to learn via these experiments and evaluations about both the potential and the future development needs of the dataset.

5. Conclusions

In this paper we described the Brazilian Linked Rainforest Data. We argue that the version 2.0 of the Brazilian Amazon Linked Rainforest Data to be a major step in having open and linked data about the ecological, economical and social dimensions related to and about the Brazilian Amazon Rainforest. The data has been published using the Linked Open Data principles. The dataset provides a centralized, structured and heterogeneous source of information. We have the aim that it facilitates the access to important data for research and thus gives a valuable support to make scientific analysis of the Brazilian Amazon Rainforest. The emerging application scenarios such as statistical and visual analysis show that the dataset has a practical value.
