Abstract

We address the issue of Ontology-Based Data Access, with ontologies represented in the framework of existential rules, also known as Datalog+/. A well-known approach involves rewriting the query using ontological knowledge. We focus here on the basic rewriting technique which consists of rewriting the initial query into a union of conjunctive queries. First, we study a generic breadth-first rewriting algorithm, which takes as input any rewriting operator, and define properties of rewriting operators that ensure the correctness of the algorithm. Then, we focus on piece-unifiers, which provide a rewriting operator with the desired properties. Finally, we propose an implementation of this framework and report some experiments.

1 Introduction

We address the issue of Ontology-Based Data Access, which aims at exploiting knowledge expressed in ontologies while querying data. In this paper, ontologies are represented in the framework of existential rules [BLMS11, KR11], also known as Datalog± [CGK08, CGL09]. Existential rules allow one to assert the existence of new unknown individuals, which is a key feature in an open-world perspective, where data are incompletely represented. These rules are of the form $body \rightarrow head$, where the body and the head are conjunctions of atoms (without functions) and variables that occur only in the head are *existentially* quantified. They generalize lightweight description logics (DLs), which form the core of the tractable profiles of OWL2.

The general query answering problem can be expressed as follows: given a knowledge base (KB) \mathcal{K} composed of a set of facts -or data- and an ontology (a set of existential rules here), and a query Q , compute the set of answers to Q in \mathcal{K} . In this paper, we consider Boolean conjunctive queries (Boolean CQs or BCQs). Note however that all our results are easily extended to non-Boolean conjunctive queries as well as to unions of conjunctive queries. The fundamental problem, called BCQ entailment hereafter, can be recast as follows: given a KB \mathcal{K} composed of facts and existential rules, and a Boolean conjunctive query Q , is Q entailed by \mathcal{K} ?

*This work was done when M. Thomazo was a PhD student at University Montpellier 2.

Figure 1: Forward / Backward Chaining

BCQ entailment is undecidable for general existential rules. There has been an intense research effort aimed at finding decidable subsets of rules that provide good tradeoffs between expressivity and complexity of query answering (see e.g. [Mug11] for a synthesis). With respect to lightweight DLs, these decidable rule fragments are more powerful and flexible. In particular, they have unrestricted predicate arity, while DLs consider unary and binary predicates only, which allows one for a natural coupling with database schemas, in which relations may have any arity; moreover, adding pieces of information, for instance to take contextual knowledge into account, is made easier by the unrestricted predicate arity, since they can be added as new predicate arguments.

There are two main approaches to solve BCQ entailment, which are linked to the classical paradigms for processing rules, namely forward and backward chaining, schematized in Figure 1. Both can be seen as ways of reducing the problem to a classical database query answering problem by eliminating the rules. The first approach consists in applying the rules to the data, thus materializing entailed facts into the data. Then, Q is entailed by \mathcal{K} if and only if it can be mapped to this materialized database. The second approach consists in using the rules to rewrite the query into a first-order query (typically a union of conjunctive queries [CGL⁺07, PUHM09, GOP11, VSS12, RMC12]) or a non-recursive Datalog program [RA10, GS12]. Then, Q is entailed by \mathcal{K} if and only if the rewritten query is entailed by the initial database. Materialization has the advantage of enabling efficient query answering but may be not appropriate for size, data access rights or data maintenance reasons. Query rewriting has the advantage of avoiding changes in the data, however its drawback is that the rewritten query may be large, even exponential in the size of initial query, hence less efficiently processed, at least with current database techniques. Finally, techniques combining both approaches have been developed, in particular so-called combined approach [LTW09, KLT⁺11].

In this paper, we focus on rewriting techniques, and more specifically on rewriting the initial conjunctive query Q into a union of conjunctive queries, that we will see as a *set* of conjunctive queries, called *rewritings* of Q . While previously cited work focuses on specific rule sublanguages, we consider general existential rules. The goal is to compute a set of rewritings both *sound* (if one of its elements maps to the initial database, then \mathcal{K} entails Q) and *complete* (if \mathcal{K} entails Q then there is an element that maps to the initial database). Minimality may also be a desirable property. In particular, let us consider the generalization relation (a preorder) induced on Boolean conjunctive queries by homomorphism: we say that Q_1 is more general than Q_2 if there is a homomorphism from Q_1 to Q_2 ; it is well-known that the existence of such

a homomorphism is equivalent to the following property: for any set of facts F , if the answer to Q_2 in F is positive so is the answer to Q_1 . We point out that any sound and complete set of rewritings of a query Q remains sound and complete when it is restricted to its most general elements. Since BCQ entailment is undecidable, there is no guarantee that such a *finite* set exists for a given query and general existential rules. A set of existential rules ensuring that a finite sound and complete set of most general rewritings exists for *any* query is called a *finite unification set (fus)* [BLMS11]. The *fus* property is not recognizable [BLMS11], but several easily recognizable *fus* classes have been exhibited in the literature: atomic-body rules [BLMS09], also known as linear TGDs [CGL09], multi-linear [CGL12], (join-)sticky rules [CGP10], weakly-recursive rules [CR12] and sets of rules with an acyclic graph of rule dependencies [BLMS09].

Paper contributions. We start from a generic algorithm which, given a BCQ and a set of existential rules, computes a rewriting set. This task can be recast in terms of exploring a potentially infinite space of queries, composed of the initial conjunctive query and its (sound) rewritings, structured by the generalization preorder. The algorithm explores this space in a breadth-first way, with the aim of computing a complete set of rewritings. It maintains a set of rewritings \mathcal{Q} and iteratively performs the following tasks: (1) generate all the one-step rewritings from unexplored queries in \mathcal{Q} ; (2) add these rewritings to \mathcal{Q} and update \mathcal{Q} in order to keep only incomparable most general elements. We call *rewriting operator* the function that, given a query and a set of rules, returns the one-step rewritings of this query. Note that it may be the case that the set of sound rewritings of the query is infinite while the set of its most general sound rewritings is finite. It follows that a simple breadth-first exploration of the rewriting space is not sufficient to ensure finiteness of the process, even for *fus* rules; one also has to maintain a set of the most general rewritings. This algorithm is generic in the sense that it is not restricted to a particular kind of existential rules nor to a specific rewriting operator.

This algorithmic scheme established, we then asked ourselves the following questions:

1. Assuming that the algorithm outputs a finite sound and complete rewriting set of pairwise incomparable queries, is this set of minimal cardinality, in the sense that no sound and complete set of rewritings produced by any other algorithm can be strictly smaller?
2. At each step of the algorithm, some queries are discarded, because they are more specific than other rewritings, even if they have not been explored yet. The question is whether this dynamic pruning of the search space keeps the completeness of the output. More generally, which properties have to be fulfilled by the operator to ensure the correctness of the algorithm and its termination for *fus* rules?
3. Finally, design a rewriting operator that fulfills the desired properties and leads to the effective computation of the rewriting set.

With respect to the first question, we show that all sound and complete rewriting sets restricted to their most general elements have the *same* cardinality, which is minimal with respect to the completeness property. If we moreover delete redundant atoms from the obtained CQs (which can be performed by a linear number of homomorphism tests for each query), we obtain a unique minimal sound and complete set of CQs of minimal size; unicity is of course up to a bijective variable renaming.

To answer the second question, we define several properties that a rewriting operator has to satisfy and show that these properties actually ensure the correctness of the algorithm and its halting for *fus* rules. In particular, we point out that the fact that a query may be removed from the rewriting set before being explored may prevent the completeness of the output, even if the rewriting operator is theoretically able to generate a complete output. The *prunability* of the rewriting operator ensures that this dynamic pruning can be safely performed. Briefly, this property holds if, for all queries Q_1 and Q_2 , when Q_1 is more general than Q_2 then any one-step rewriting of Q_2 is less general than Q_1 itself or one of the one-step rewritings of Q_1 ; intuitively, this allows to discard the rewriting Q_2 even when its one-step rewritings have not been generated yet. Note that this kind of properties ties in with an issue raised in [ISG12] about the gap between theoretical completeness of some methods and the effective completeness of their implementation, this gap being mainly due to algorithmic optimizations (here the dynamic pruning).

Concerning the third question, we proceed in several steps. First, we rely on a specific unifier, called a *piece-unifier*, that was designed for backward chaining with conceptual graph rules (whose logical translation is exactly existential rules [SM96]). As in classical backward chaining, the rewriting process relies on a unification operation between the current query and a rule head. However, existential variables in rule heads induce a structure that has to be considered to keep soundness. Thus, instead of unifying a single atom of the query at once, our unifier processes a subset of atoms from the query. We call *piece* a minimal subset of atoms from the query that have to be erased together, hence the name piece-unifier. We present below a very simple example of piece unification (in particular, the head of the existential rule is restricted to a single atom).

Example 1 Let $R = \forall x (q(x) \rightarrow \exists y p(x, y))$ and the BCQ $Q = \exists u \exists v \exists w (p(u, v) \wedge p(w, v) \wedge r(u, w))$. Assume we want to unify the atom $p(u, v)$ from Q with $p(x, y)$, for instance by a substitution $\{(u, x), (v, y)\}$. Since v is unified with the existential variable y , all other atoms from Q containing v must also be considered: indeed, simply rewriting Q into $Q_1 = q(x) \wedge p(w, y) \wedge r(x, w)$ would be unsound: intuitively, the fact that the atoms $p(u, v)$ and $p(w, v)$ in Q share a variable would be lost in atoms $q(x)$ and $p(w, y)$; for instance $F = q(a) \wedge p(b, c) \wedge r(a, b)$ would answer Q_1 despite Q is not entailed by F and R . Thus, $p(u, v)$ and $p(w, v)$ have to be both unified with the head of R , for instance by means of the following substitution: $\mu = \{(u, x), (v, y), (w, x)\}$. $\{p(u, v), p(w, v)\}$ is called a *piece*. The corresponding rewriting of Q is $q(x) \wedge r(x, x)$.

Piece-unifiers lead to a logically sound and complete rewriting method. As far as we know, it is the only method accepting any kind of existential rules, while staying in this fragment, i.e., without Skolemization of rule heads to replace existential variables with Skolem functions.

We show that the piece-based rewriting operator fulfills the desired properties ensuring the correctness of the generic algorithm and its termination in the case of *fus* rules. The next question was how to optimize the rewriting step. Indeed, the problem of deciding whether there is a piece-unifier between a query and a rule head is NP-complete and the number of piece-unifiers can be exponential in the size of the query. To cope with these sources of complexity, we consider so-called *single-piece* unifiers, which unify a single-piece of the query at once (like μ in Example 1). We also focus on rules with a head restricted to an atom. This is not a restriction in terms of expressivity, since any rule can be decomposed into an equivalent set of atomic-head rules by simply

introducing a new predicate for each rule (e.g. [CGK08], [BLMS09]). The interesting point is that each atom in Q belongs to at most one piece with respect to R when R has an atomic head (which is false for general existential rules). In the case of rules with atomic head, the number of (most general) single-piece unifiers of a query Q with the head of a rule R is bounded by the size of the query. We show that the single-piece based rewriting operator is able to generate a sound and complete set of rewritings. However, as pointed out in several examples, it is not prunable. Hence, single-piece unifiers have to be combined to recover prunability. We thus define the *aggregation* of single-piece unifiers and show that the corresponding rewriting operator fulfills all desired properties and generates less queries than the piece-based rewriting operator. Detailed algorithms are given and first experiments are reported.

Paper organization. Section 2 recalls some basic notions about the existential rule framework. Section 3 defines sound, complete and minimal sets of rewritings. In Section 4 the generic breadth-first algorithm is introduced and general properties of rewriting operators are studied. Section 5 presents the piece-based rewriting operator. In Section 6, we focus on exploiting single-piece unifiers and introduce the rewriting operator based on their aggregation. Finally, Section 7.2 is devoted to implementation and experiments, as well as to further work.

This is an extended version of papers by the same authors published at RR 2012 and RR 2013 (International Conference on Web Reasoning and Rule Systems).

2 Preliminaries

An *atom* is of the form $p(t_1, \dots, t_k)$ where p is a predicate with arity k , and the t_i are terms, i.e., variables or constants. Given an atom or a set of atoms A , $\text{vars}(A)$, $\text{consts}(A)$ and $\text{terms}(A)$ denote its set of variables, of constants and of terms, respectively. In all the examples in this paper, the terms are variables (denoted by x, y, z , etc.). \models denotes the classical logical consequence. Two formulas f_1 and f_2 are said to be equivalent if $f_1 \models f_2$ and $f_2 \models f_1$.

A *fact* is an existentially closed conjunction of atoms.¹ A *conjunctive query* (CQ) is an existentially quantified conjunction of atoms. When it is a closed formula, it is called a *Boolean CQ* (BCQ). Hence facts and BCQs have the same logical form. In the following, we will see them as sets of atoms. Given sets of atoms A and B , a *homomorphism* h from A to B is a substitution of $\text{vars}(A)$ by $\text{terms}(B)$ s.t. $h(A) \subseteq B$. We say that A is *mapped* to B by h . If there is a homomorphism from A to B , we say that A is *more general* than B , which is denoted $A \geq B$.

Given a fact F and a BCQ Q , the answer to Q in F is *positive* if $F \models Q$. It is well-known that $F \models Q$ if and only if there is a homomorphism from Q to F . If Q is a non-Boolean CQ, let $x_1 \dots x_q$ be the free variables in Q . Then, a tuple of constants $(a_1 \dots a_q)$ is an answer to Q in F if there is a homomorphism from Q to F that maps x_i to a_i for each i . In other words, $(a_1 \dots a_q)$ is an answer to Q in F if and only if the answer to the BCQ obtained from Q by substituting each x_i with a_i is positive.

In this paper, we consider only Boolean queries for simplicity reasons. This is not a restriction, since our mechanisms can actually process a CQ with free variables $x_1 \dots x_q$ by translating it into a BCQ with an added atom $\text{ans}(x_1 \dots x_q)$, where ans is a special predicate not occurring in the knowledge base. Since ans can never be erased

¹We generalize the classical notion of a fact in order to take existential variables into account.

by a rewriting step, the x_i can only be substituted and will not “disappear”. We can thus compute the set of rewritings of a CQ as a Boolean CQ with a special *ans* atom, then transform the rewritings into non-Boolean CQs by removing the *ans* atom and consider its arguments as free variables. Note that our the generic algorithm can accept as input a union of conjunctive queries as well, since it works exactly in the same way if it takes as input a set of CQs instead of a single CQ.

Definition 1 (Existential rule) An existential rule (or simply a rule) is a formula $R = \forall \vec{x} \forall \vec{y} (B[\vec{x}, \vec{y}] \rightarrow \exists \vec{z} H[\vec{y}, \vec{z}])$ where \vec{x}, \vec{y} and \vec{z} are tuple of variables, $B = \text{body}(R)$ and $H = \text{head}(R)$ are conjunctions of atoms, resp. called the body and the head of R . The frontier of R , noted $\text{fr}(R)$, is the set $\text{vars}(B) \cap \text{vars}(H) = \vec{y}$. The set of existential variables in R is the set $\text{vars}(H) \setminus \text{fr}(R) = \vec{z}$.

In the following, we will omit quantifiers in rules as there is no ambiguity.

A knowledge base (KB) $\mathcal{K} = (F, \mathcal{R})$ is composed of a fact F and a finite set of existential rules \mathcal{R} . The BCQ entailment problem takes as input a KB $\mathcal{K} = (F, \mathcal{R})$ and a BCQ Q , and asks if $F, \mathcal{R} \models Q$ holds.

3 Desirable Properties of Rewriting Sets

Given a query Q and a set of existential rules \mathcal{R} , rewriting techniques compute a set of queries \mathcal{Q} , which we call a *rewriting set* hereafter. It is generally desired that such a set satisfies at least three properties: *soundness*, *completeness* and *minimality*.

Definition 2 (Sound and Complete set) Let \mathcal{R} be a set of existential rules and Q be a BCQ. Let \mathcal{Q} be a set of BCQs. \mathcal{Q} is said to be sound w.r.t. Q and \mathcal{R} if for all facts F , for all $Q' \in \mathcal{Q}$, if Q' can be mapped to F then $(\mathcal{R}, F \models Q)$. Reciprocally, \mathcal{Q} is said to be complete w.r.t. Q and \mathcal{R} if for all fact F , if $(\mathcal{R}, F \models Q)$ then there is $Q' \in \mathcal{Q}$ s.t. Q' can be mapped to F .

We mentioned in the introduction that only the *most general elements* of a rewriting set need to be considered. Indeed, let Q_1 and Q_2 be two elements of a rewriting set such that $Q_1 \geq Q_2$ and let F be any fact: if Q_1 maps to F , then Q_2 is useless; if Q_1 does not map to F , neither does Q_2 ; thus removing Q_2 will not undermine completeness (and it will not undermine soundness either). The output of a rewriting algorithm should thus be a minimal set of incomparable queries that “covers” the set of all the sound rewritings of the initial query.

Definition 3 (Covering relation) Let \mathcal{Q}_1 and \mathcal{Q}_2 be two sets of BCQs. \mathcal{Q}_1 covers \mathcal{Q}_2 , which is denoted $\mathcal{Q}_1 \geq \mathcal{Q}_2$, if for all $Q_2 \in \mathcal{Q}_2$ there is $Q_1 \in \mathcal{Q}_1$ with $Q_1 \geq Q_2$.

Definition 4 (Minimal set of BCQs, Cover) Let \mathcal{Q} be a set of BCQs. \mathcal{Q} is said to be minimal if there is no $Q \in \mathcal{Q}$ such that $(\mathcal{Q} \setminus \{Q\}) \geq \mathcal{Q}$. A cover of \mathcal{Q} is a minimal set $\mathcal{Q}^c \subseteq \mathcal{Q}$ such that $\mathcal{Q}^c \geq \mathcal{Q}$.

Since a cover is a minimal set, its elements are pairwise incomparable.

Example 2 See also Figure 2. Let $\mathcal{Q} = \{Q_1, \dots, Q_6\}$ and the following preorder over \mathcal{Q} : $Q_1 \geq Q_2, Q_4, Q_5, Q_6$; $Q_2 \geq Q_1, Q_4, Q_5, Q_6$; $Q_3 \geq Q_4$; $Q_5 \geq Q_6$ (note that Q_1 and Q_2 are equivalent). There are two covers of \mathcal{Q} , namely $\{Q_1, Q_3\}$ and $\{Q_2, Q_3\}$.

Figure 2: Cover (Example 2)

A set of (sound) rewritings may have a finite cover even when it is infinite, as illustrated by Example 3.

Example 3 Let $Q = t(u)$, $R_1 = t(x) \wedge p(x, y) \rightarrow r(y)$, $R_2 = r(x) \wedge p(x, y) \rightarrow t(y)$. R_1 and R_2 have a head restricted to a single atom and no existential variable, hence the classical most general unifier can be used, which unifies the first atom in the query with the atom of a rule head. The set of rewritings of Q with $\{R_1, R_2\}$ is infinite. The first generated queries are the following (note that rule variables are renamed when needed):

$$Q_0 = t(u)$$

$$Q_1 = r(x) \wedge p(x, y) \text{ // from } Q_0 \text{ and } R_2 \text{ with } \{(u, y)\}$$

$$Q_2 = t(x_0) \wedge p(x_0, y_0) \wedge p(y_0, y) \text{ // from } Q_1 \text{ and } R_1 \text{ with } \{(x, y_0)\}$$

$$Q_3 = r(x_1) \wedge p(x_1, y_1) \wedge p(y_1, y_0) \wedge p(y_0, y) \text{ // from } Q_2 \text{ and } R_2 \text{ with } \{(x_0, y_1)\}$$

$$Q_4 = t(x_2) \wedge p(x_2, y_2) \wedge p(y_2, y_1) \wedge p(y_1, y_0) \wedge p(y_0, y) \text{ // from } Q_3 \text{ and } R_1$$

and so on . . .

However, the set of the most general rewritings is $\{Q_0, Q_1\}$ since any other query than can be obtained is more specific than Q_0 or Q_1 .

It can be easily checked that all covers of a given set have the same cardinality. We now prove that this property can be extended to the covers of all sound and complete finite rewriting sets of Q , no matter of the rewriting technique used to compute these sets.

Theorem 1 Let \mathcal{R} be a set of rules and Q be a BCQ. Any finite cover of a sound and complete rewriting set of Q with \mathcal{R} is of minimal cardinality (among all sound and complete rewriting sets of Q).

Proof: Let Q_1 and Q_2 be two arbitrary sound and complete rewriting sets of Q with \mathcal{R} , and Q_1^c and Q_2^c be one of their respective finite covers. Q_1^c and Q_2^c are also sound and complete, and are of smaller cardinality. We show that they have the same cardinality. Let $Q_1 \in Q_1^c$. There exists $Q_2 \in Q_2^c$ such that $Q_2 \geq Q_1$. If not, Q would be entailed by $F = Q_1$ and \mathcal{R} since Q_1^c is a sound rewriting set of Q (and Q_1 maps to itself), but no elements of Q_2^c would map to F : thus, Q_2^c would not be complete. Similarly, there exists $Q_1' \in Q_1^c$ such that $Q_1' \geq Q_2$. Then $Q_1' \geq Q_1$, which implies that $Q_1' = Q_1$

by assumption on Q_1^c . For all $Q_1 \in Q_1^c$, there exists $Q_2 \in Q_2^c$ such that $Q_2 \geq Q_1$ and $Q_1 \geq Q_2$. Such a Q_2 is unique: indeed, two such elements would be comparable for \geq , which is not possible by construction of Q_2^c . The function associating Q_2 with Q_1 is thus a bijection from Q_1^c to Q_2^c , which shows that these two sets have the same cardinality. \square

Furthermore, the proof of the preceding theorem shows that, given any two sound and complete rewriting sets of Q , there is a bijection from any cover of the first set to any cover of the second set such that two elements in relation by the bijection are equivalent. However, these elements are not necessarily isomorphic (i.e., equal up to a variable renaming) because they may contain redundancies. Consider the preorder induced by homomorphism on the set of all BCQs definable on some vocabulary. It is well-known that this preorder is such that any of its equivalence classes possesses a unique element of minimal size (up to isomorphism), called its *core* (notion introduced for graphs, but easily transferable to queries). Every query can be transformed into its equivalent core by removing redundant atoms. We recall that a set of existential rules ensuring that a finite sound and complete set of most general rewritings exists for any query is called a finite unification set (*fus*).²

From previous remark and Theorem 1, we obtain:

Corollary 1 *Let \mathcal{R} be a fus and Q be a BCQ. There is a unique finite sound and complete rewriting set of Q with \mathcal{R} that has both minimal cardinality and elements of minimal size.*

4 A Generic Breadth-First Algorithm

We will now present a generic rewriting algorithm that takes as input a set of existential rules and a query, and as parameter a *rewriting operator*. The studied question is the following: which properties should this operator fulfill in order that the algorithm outputs a sound, complete, finite and minimal set?

4.1 Algorithm

Definition 5 (Rewriting operator) *A rewriting operator rew is a function which takes as input a conjunctive query Q and a set of rules \mathcal{R} and outputs a set of conjunctive queries denoted by $rew(Q, \mathcal{R})$.*

Since the elements of $rew(Q, \mathcal{R})$ are queries, it is possible to apply further steps of rewriting to them. This naturally leads to the notions of k -rewriting and k -saturation.

Definition 6 (k -rewriting) *Let Q be a conjunctive query, \mathcal{R} be a set of rules and rew be a rewriting operator. A 1-rewriting of Q (w.r.t. rew and \mathcal{R}) is an element of $rew(Q, \mathcal{R})$. A k -rewriting of Q , for $k > 1$, (w.r.t. rew and \mathcal{R}) is a 1-rewriting of a $(k - 1)$ -rewriting of Q .*

The term k -saturation is convenient to name the set of queries that can be obtained in at most k rewriting steps.

²The finite unification set notion was first introduced in [BLMS09] and defined with respect to piece-unifiers. However, since piece-unifiers provide a sound and complete rewriting operator, as recalled in Section 5, and all the covers of a given set have the same cardinality, both definitions are equivalent.

Definition 7 (*k*-saturation) Let Q be a query, \mathcal{R} be a set of rules and rew be a rewriting operator. We denote by $\text{rew}_k(Q, \mathcal{R})$ the set of k -rewritings of Q . We call k -saturation, and denote by $W_k(Q, \mathcal{R})$, the set of i -rewritings of Q for all $i \leq k$. We denote $W_\infty(Q, \mathcal{R}) = \bigcup_{k \in \mathbb{N}} W_k(Q, \mathcal{R})$.

In the following, we extend the notations rew , rew_k and W_k to a set of queries \mathcal{Q} instead of a single query Q : $\text{rew}(\mathcal{Q}, \mathcal{R}) = \bigcup_{Q \in \mathcal{Q}} \text{rew}(Q, \mathcal{R})$, $\text{rew}_k(\mathcal{Q}, \mathcal{R}) = \bigcup_{Q \in \mathcal{Q}} \text{rew}_k(Q, \mathcal{R})$ and $W_k(\mathcal{Q}, \mathcal{R}) = \bigcup_{i \leq k} \text{rew}_i(\mathcal{Q}, \mathcal{R})$.

Algorithm 1 performs a breadth-first exploration of the rewriting space of a given query. At each step, only the most general elements are kept thanks to a covering function, denoted by cover , that computes a cover of a given set. For termination reasons (see the proof of Property 2), we require that if both $\mathcal{Q}_c \cup \{q\}$ and $\mathcal{Q}_c \cup \{q'\}$ are covers of $\mathcal{Q}_F \cup \text{rew}(\mathcal{Q}_E, \mathcal{R})$, with q and q' homomorphically equivalent and $\{q\}$ belongs to \mathcal{Q}_F , then cover does not output $\mathcal{Q}_c \cup \{q'\}$ – which intuitively means that queries already explored are preferred to non-explored queries in the choice of a cover. If rew fulfills some good properties (subsequently specified), then after the i^{th} iteration of the while loop the i -saturation of Q (with respect to \mathcal{R} and rew) is covered by \mathcal{Q}_F , while \mathcal{Q}_E contains the queries that remain to be explored.

Algorithm 1: A GENERIC BREADTH-FIRST REWRITING ALGORITHM

Data: A set of rules \mathcal{R} , a BCQ Q
Access: A rewriting operator rew , a covering function cover
Result: A cover of the set of all the rewritings of Q
 $\mathcal{Q}_F \leftarrow \{Q\};$ // resulting set
 $\mathcal{Q}_E \leftarrow \{Q\};$ // queries to be explored
while $\mathcal{Q}_E \neq \emptyset$ **do**
 $\mathcal{Q}_C \leftarrow \text{cover}(\mathcal{Q}_F \cup \text{rew}(\mathcal{Q}_E, \mathcal{R}));$ // update cover
 $\mathcal{Q}_E \leftarrow \mathcal{Q}_C \setminus \mathcal{Q}_F;$ // select unexplored queries
 $\mathcal{Q}_F \leftarrow \mathcal{Q}_C;$
return \mathcal{Q}_F

In the remainder of this section, we study the conditions that a rewriting operator must meet in order that: (i) the algorithm halts and outputs a cover of all the rewritings that can be obtained with this rewriting operator, provided that such a finite cover exists; (ii) the output cover is sound and complete.

4.2 Correctness and Termination of the Algorithm

We now exhibit a sufficient property on the rewriting operator that ensures that Algorithm 1 outputs a cover of $W_\infty(Q, \mathcal{R})$.

Definition 8 (Prunable) Let rew be a rewriting operator. rew is prunable if for any set of rules \mathcal{R} and for all queries Q_1, Q_2, Q'_2 such that $Q_1 \geq Q_2$, $Q'_2 \in \text{rew}(Q_2, \mathcal{R})$ and $Q_1 \not\geq Q'_2$, there is $Q'_1 \in \text{rew}(Q_1, \mathcal{R})$ such that $Q'_1 \geq Q'_2$.

Intuitively, if an operator is prunable then it is guaranteed that for every Q_1 more general than Q_2 , the one-step rewritings of Q_2 are covered by the one-step rewritings of Q_1 or by Q_1 itself. The following lemma states that this can be generalized to k -rewritings for any k .

Lemma 1 *Let rew be a prunable rewriting operator, and let \mathcal{Q}_1 and \mathcal{Q}_2 be two sets of queries. If $\mathcal{Q}_1 \geq \mathcal{Q}_2$, then $W_\infty(\mathcal{Q}_1, \mathcal{R}) \geq W_\infty(\mathcal{Q}_2, \mathcal{R})$.*

Proof: We prove by induction on i that $W_i(\mathcal{Q}_1, \mathcal{R}) \geq \text{rew}_i(\mathcal{Q}_2, \mathcal{R})$.

For $i = 0$, $W_0(\mathcal{Q}_1, \mathcal{R}) = \mathcal{Q}_1 \geq \mathcal{Q}_2 = \text{rew}_0(\mathcal{Q}_2, \mathcal{R})$.

For $i > 0$, for any $Q_2 \in \text{rew}_i(\mathcal{Q}_2, \mathcal{R})$, there is $Q'_2 \in \text{rew}_{i-1}(\mathcal{Q}_2, \mathcal{R})$ such that $Q_2 \in \text{rew}(Q'_2, \mathcal{R})$. By induction hypothesis, there is $Q'_1 \in W_{i-1}(\mathcal{Q}_1, \mathcal{R})$ such that $Q'_1 \geq Q'_2$. rew is prunable, thus either $Q'_1 \geq Q_2$ or there is $Q_1 \in \text{rew}(Q'_1, \mathcal{R})$ such that $Q_1 \geq Q_2$. Since $W_{i-1}(\mathcal{Q}_1, \mathcal{R})$ and $\text{rew}(Q'_1, \mathcal{R})$ are both included in $W_i(\mathcal{Q}_1, \mathcal{R})$, we can conclude. \square

This lemma would not be sufficient to prove the correctness of Algorithm 1, as will be discussed in Section 6.1. We need a stronger version, which checks that a query whose 1-rewritings are covered needs not to be explored.

Lemma 2 *Let rew be a prunable rewriting operator, and let \mathcal{Q}_1 and \mathcal{Q}_2 be two sets of queries. If $(\mathcal{Q}_1 \cup \mathcal{Q}_2) \geq \text{rew}(\mathcal{Q}_1, \mathcal{R})$, then $(\mathcal{Q}_1 \cup W_\infty(\mathcal{Q}_2, \mathcal{R})) \geq W_\infty(\mathcal{Q}_1 \cup \mathcal{Q}_2, \mathcal{R})$.*

Proof: We prove by induction on i that $\mathcal{Q}_1 \cup W_i(\mathcal{Q}_2, \mathcal{R}) \geq \text{rew}_i(\mathcal{Q}_1 \cup \mathcal{Q}_2, \mathcal{R})$.

For $i = 0$, $\text{rew}_0(\mathcal{Q}_1 \cup \mathcal{Q}_2, \mathcal{R}) = \mathcal{Q}_1 \cup \mathcal{Q}_2 = \mathcal{Q}_1 \cup W_0(\mathcal{Q}_2, \mathcal{R})$.

For $i > 0$, for any $Q_i \in \text{rew}_i(\mathcal{Q}_1 \cup \mathcal{Q}_2, \mathcal{R})$, there is $Q_{i-1} \in \text{rew}_{i-1}(\mathcal{Q}_1 \cup \mathcal{Q}_2, \mathcal{R})$ such that $Q_i \in \text{rew}(Q_{i-1}, \mathcal{R})$. By induction hypothesis, there is $Q'_{i-1} \in \mathcal{Q}_1 \cup W_{i-1}(\mathcal{Q}_2, \mathcal{R})$ such that $Q'_{i-1} \geq Q_{i-1}$. Since rew is prunable, either $Q'_{i-1} \geq Q_i$ or there is $Q'_i \in \text{rew}(Q'_{i-1}, \mathcal{R})$ such that $Q'_i \geq Q_i$. Then, there are two possibilities:

- either $Q'_{i-1} \in \mathcal{Q}_1$: since $\mathcal{Q}_1 \cup \mathcal{Q}_2 \geq \text{rew}(\mathcal{Q}_1, \mathcal{R})$, we have $\mathcal{Q}_1 \cup \mathcal{Q}_2 \geq \{Q'_i\}$ and so $\mathcal{Q}_1 \cup W_i(\mathcal{Q}_2, \mathcal{R}) \geq \{Q'_i\}$.
- or $Q'_{i-1} \in W_{i-1}(\mathcal{Q}_2, \mathcal{R})$: then $Q'_i \in W_i(\mathcal{Q}_2, \mathcal{R})$.

\square

Finally, the correctness of Algorithm 1 is based on the following loop invariants.

Property 1 (Invariants of Algorithm 1) *Let rew be a rewriting operator. After each iteration of the while loop of Algorithm 1, the following properties hold:*

1. $\mathcal{Q}_E \subseteq \mathcal{Q}_F \subseteq W_\infty(Q, \mathcal{R})$;
2. $\mathcal{Q}_F \geq \text{rew}(\mathcal{Q}_F \setminus \mathcal{Q}_E, \mathcal{R})$;
3. if rew is prunable then $(\mathcal{Q}_F \cup W_\infty(\mathcal{Q}_E, \mathcal{R})) \geq W_\infty(Q, \mathcal{R})$;
4. for all distinct $Q, Q' \in \mathcal{Q}_F$, $Q \not\geq Q'$ and $Q' \not\geq Q$.

Proof: Invariants are proved by induction on the number of iterations of the while loop. Below \mathcal{Q}_F^i and \mathcal{Q}_E^i denote the value of \mathcal{Q}_F and \mathcal{Q}_E after i iterations.

Invariant 1: $\mathcal{Q}_E \subseteq \mathcal{Q}_F \subseteq W_\infty(Q, \mathcal{R})$.

basis: $\mathcal{Q}_E^0 = \mathcal{Q}_F^0 = \{Q\} = W_0(Q, \mathcal{R}) \subseteq W_\infty(Q, \mathcal{R})$.

induction step: by construction, $\mathcal{Q}_E^i \subseteq \mathcal{Q}_F^i$ and $\mathcal{Q}_F^i \subseteq \mathcal{Q}_F^{i-1} \cup \text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R})$.

For any $Q' \in \mathcal{Q}_F^i$ we have: either $Q' \in \mathcal{Q}_F^{i-1}$ and then by induction hypothesis $Q' \in W_\infty(Q, \mathcal{R})$; or $Q' \in \text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R})$ and then by induction hypothesis we have $\mathcal{Q}_E^{i-1} \subseteq W_\infty(Q, \mathcal{R})$, which implies $Q' \in W_\infty(Q, \mathcal{R})$.

Invariant 2: $\mathcal{Q}_F \geq \text{rew}(\mathcal{Q}_F \setminus \mathcal{Q}_E, \mathcal{R})$.

basis: $\text{rew}(\mathcal{Q}_F^0 \setminus \mathcal{Q}_E^0, \mathcal{R}) = \text{rew}(\emptyset, \mathcal{R}) = \emptyset$ and any set covers it.

induction step: by construction, $\mathcal{Q}_F^i \geq \mathcal{Q}_F^{i-1} \cup \text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R})$; since by induction hypothesis $\mathcal{Q}_F^{i-1} \geq \text{rew}(\mathcal{Q}_F^{i-1} \setminus \mathcal{Q}_E^{i-1}, \mathcal{R})$, we have $\mathcal{Q}_F^i \geq \text{rew}(\mathcal{Q}_F^{i-1} \setminus \mathcal{Q}_E^{i-1}, \mathcal{R}) \cup \text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R}) = \text{rew}(\mathcal{Q}_F^{i-1}, \mathcal{R})$. Furthermore, by construction, $\mathcal{Q}_E^i = \mathcal{Q}_F^i \setminus \mathcal{Q}_F^{i-1}$; thus $\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i \subseteq \mathcal{Q}_F^{i-1}$ and so $\text{rew}(\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i, \mathcal{R}) \subseteq \text{rew}(\mathcal{Q}_F^{i-1}, \mathcal{R})$. Thus $\mathcal{Q}_F^i \geq \text{rew}(\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i, \mathcal{R})$.

Invariant 3: if rew is prunable then $(\mathcal{Q}_F \cup W_\infty(\mathcal{Q}_E, \mathcal{R})) \geq W_\infty(Q, \mathcal{R})$.

basis: $(\mathcal{Q}_F^0 \cup W_\infty(\mathcal{Q}_E^0, \mathcal{R})) = (\{Q\} \cup W_\infty(\{Q\}, \mathcal{R})) = W_\infty(Q, \mathcal{R})$.

induction step: we first show that (i): $(\mathcal{Q}_F^i \cup W_\infty(\mathcal{Q}_E^i, \mathcal{R})) \geq W_\infty(\mathcal{Q}_F^i, \mathcal{R})$, then we prove by induction that (ii): $W_\infty(\mathcal{Q}_F^i, \mathcal{R}) \geq W_\infty(Q, \mathcal{R})$:

(i) by construction $\mathcal{Q}_E^i \subseteq \mathcal{Q}_F^i$, thus $(\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i) \cup \mathcal{Q}_E^i = \mathcal{Q}_F^i$, and by Invariant 2, we have $(\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i) \cup \mathcal{Q}_E^i \geq \text{rew}(\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i, \mathcal{R})$. Lemma 2 then entails that $((\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i) \cup W_\infty(\mathcal{Q}_E^i, \mathcal{R})) \geq W_\infty((\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i) \cup \mathcal{Q}_E^i, \mathcal{R})$ and we can conclude since $\mathcal{Q}_F^i = (\mathcal{Q}_F^i \setminus \mathcal{Q}_E^i) \cup \mathcal{Q}_E^i$.

(ii) by construction, we have $\mathcal{Q}_F^i \geq \mathcal{Q}_F^{i-1} \cup \text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R})$; so, by Lemma 1, we have $W_\infty(\mathcal{Q}_F^i, \mathcal{R}) \geq W_\infty(\mathcal{Q}_F^{i-1} \cup \text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R}), \mathcal{R}) = W_\infty(\mathcal{Q}_F^{i-1}, \mathcal{R}) \cup W_\infty(\text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R}), \mathcal{R})$. Moreover, $\mathcal{Q}_E^{i-1} \subseteq \mathcal{Q}_F^{i-1} \subseteq W_\infty(\mathcal{Q}_F^{i-1}, \mathcal{R})$, thus $W_\infty(\mathcal{Q}_F^i, \mathcal{R}) \geq \mathcal{Q}_F^{i-1} \cup \mathcal{Q}_E^{i-1} \cup W_\infty(\text{rew}(\mathcal{Q}_E^{i-1}, \mathcal{R}), \mathcal{R}) = \mathcal{Q}_F^{i-1} \cup W_\infty(\mathcal{Q}_E^{i-1}, \mathcal{R})$. Using (i), we have $W_\infty(\mathcal{Q}_F^i, \mathcal{R}) \geq W_\infty(\mathcal{Q}_F^{i-1}, \mathcal{R})$ and conclude by induction hypothesis.

Invariant 4: for all distinct $Q, Q' \in \mathcal{Q}_F$, $Q \not\geq Q'$ and $Q' \not\geq Q$. Trivially satisfied thanks to the properties of cover .

□

The next property states that if rew is prunable then Algorithm 1 halts for each case where $W_\infty(Q, \mathcal{R})$ owns a finite cover.

Property 2 *Let rew be a rewriting operator, \mathcal{R} be a set of rules and Q be a query. If $W_\infty(Q, \mathcal{R})$ has a finite cover and rew is prunable then Algorithm 1 halts.*

Proof: Let \mathcal{Q} be a finite cover of $W_\infty(Q, \mathcal{R})$ and let m be the largest k for a k -rewriting in \mathcal{Q} . We thus have $W_m(Q, \mathcal{R}) \geq \mathcal{Q} \geq W_\infty(Q, \mathcal{R})$. Since the operator is prunable, we have $\mathcal{Q}_F^i \geq W_i(Q, \mathcal{R})$ for all $i \geq 0$ (which can be proved with a straightforward induction on i). Thus $\mathcal{Q}_F^m \geq W_\infty(Q, \mathcal{R})$. Thus, $\text{rew}(\mathcal{Q}_E^m, \mathcal{R})$ is covered by \mathcal{Q}_F^m , and since already explored queries are taken first for the computation of a cover, we have that $\mathcal{Q}_E^{m+1} = \emptyset$. Hence Algorithm 1 halts. □

Theorem 2 *Let rew be a rewriting operator, \mathcal{R} be a set of rules and Q be a query. If $W_\infty(Q, \mathcal{R})$ has a finite cover and rew is prunable then Algorithm 1 outputs this cover (up to query equivalence).*

Proof: By Property 2, Algorithm 1 halts. By Invariant 3 from Property 1, $(\mathcal{Q}_F^f \cup W_\infty(\mathcal{Q}_E^f, \mathcal{R})) \geq W_\infty(Q, \mathcal{R})$ where \mathcal{Q}_F^f and \mathcal{Q}_E^f denote the final values of \mathcal{Q}_F and \mathcal{Q}_E in Algorithm 1. Since $\mathcal{Q}_E^f = \emptyset$ when Algorithm 1 halts, we have $\mathcal{Q}_F^f \geq W_\infty(Q, \mathcal{R})$. Thanks to Invariants 1 and 4 from Property 1 we conclude that \mathcal{Q}_F^f is a cover of $W_\infty(Q, \mathcal{R})$. □

4.3 Preserving Soundness and Completeness

We consider two further properties of a rewriting operator, namely soundness and completeness, with the aim of ensuring the soundness and completeness of the obtained rewriting set within the meaning of Definition 2.

Definition 9 (Soundness/completeness of a rewriting operator) *Let rew be a rewriting operator. rew is sound if for any set of rules \mathcal{R} , for any query Q , for any $Q' \in \text{rew}(Q, \mathcal{R})$, for any fact F , $F \models Q'$ implies that $F, \mathcal{R} \models Q$. rew is complete if for any set of rules \mathcal{R} , for any query Q , for any fact F s.t. $F, \mathcal{R} \models Q$, there exists $Q' \in W_\infty(Q, \mathcal{R})$ s.t. $F \models Q'$.*

Property 3 *If rew is sound, then the output of Algorithm 1 is a sound rewriting set of Q and \mathcal{R} .*

Proof: Direct consequence of Invariant 1 from Property 1. □

Perhaps surprisingly, the completeness of the rewriting operator is not sufficient to ensure the completeness of the output rewriting set. Examples are provided in Section 6.1. This is due to the dynamic pruning performed at each step of Algorithm 1. Therefore the prunability of the operator is also required.

Property 4 *If rew is prunable and complete, then the output of Algorithm 1 is a complete rewriting set of Q and \mathcal{R} .*

Proof: Algorithm 1 returns Q_F when Q_E is empty. By Invariant 3 of Property 1, we know that $(Q_F \cup W_\infty(\emptyset, \mathcal{R})) \geq W_\infty(Q, \mathcal{R})$. Since $W_\infty(\emptyset, \mathcal{R}) = \emptyset$, we are sure that $Q_F \geq W_\infty(Q, \mathcal{R})$. □

Theorem 3 *If rew is a sound, complete and prunable operator, and \mathcal{R} is a finite unification set of rules, then for any query Q , Algorithm 1 outputs a minimal (finite) sound and complete rewriting set of Q with \mathcal{R} .*

Proof: If \mathcal{R} is a fus and rew is a sound and complete operator then $W_\infty(Q, \mathcal{R})$ has a finite cover. We conclude with Properties 3 and 4 and Theorem 2. □

5 Piece-Based Rewriting

As mentioned in the introduction (and illustrated in Example 1), existential variables in rule heads induce a structure that has to be taken into account in the rewriting mechanism. Hence the classical notion of a unifier is replaced by that of a piece-unifier [BLMS11]. A piece-unifier “unifies” a subset Q' of Q with a subset H' of $\text{head}(R)$, in the sense that the associated substitution u is such that $u(Q') = u(H')$. Given a piece-unifier, Q is partitioned into “pieces”, which are minimal subsets of atoms that must processed together. More specifically, we call *cutpoints*, the variables from Q' that are not unified with existential variables from H' (i.e., they are unified with frontier variables or constants); then a *piece* in Q is a minimal non-empty subset of atoms “glued” by variables other than cutpoints, i.e., connected by a path of variables that are not cutpoints. We recall below the definition of pieces given in [BLMS11] (where T corresponds to the set of cutpoints).

Definition 10 (Piece) [BLMS11] *Let A be a set of atoms and $T \subseteq \text{vars}(A)$. A piece of A according to T is a minimal non-empty subset P of A such that, for all a and a' in A , if $a \in P$ and $(\text{vars}(a) \cap \text{vars}(a')) \not\subseteq T$, then $a' \in P$.*

In this paper, we give a definition of a piece-unifier based on partitions rather than substitutions, which simplifies subsequent notions and proofs. For any substitution u from a set of variables E_1 to a set of terms E_2 associated with a piece-unifier, it holds that $E_1 \cap E_2 = \emptyset$. We can thus assign with u a *partition* P_u of $E_1 \cup E_2$ such that two terms are in the same class of P_u if and only if they are merged by u ; more specifically, we consider the equivalence classes of the symmetric, reflexive and transitive closure of the following relation \sim : $t \sim t'$ if $u(t) = t'$. Conversely, to a partition on a set of terms E , such that no class contains two constants, can be assigned a substitution u obtained by selecting an element of each class with priority given to constants: let $\{e_1 \dots e_k\}$ be a class in the partition and e_i be the selected element, then for all e_j with $1 \leq j \neq i \leq k$, we set $u(e_j) = e_i$. If we consider a total order on terms, such that constants are smaller than variables, then a unique substitution is obtained by taking the smallest element in each class. We call *admissible partition* a partition such that no class contains two constants.

The set of all partitions over a given set is structured in a *lattice* by the “*finer than*” relation (given two partitions P_1 and P_2 , P_1 is finer than P_2 , denoted by $P_1 \geq P_2$, if every class of P_1 is included in a class of P_2).³ The *join* of several partitions is obtained by making the union of their non-disjoint classes until stability. The join of two admissible partitions may be a non-admissible partition. We say that several admissible partitions are *compatible* if their join is an admissible partition. Note that if the concerned partitions are relative to the same set E , then their join is their *greatest lower bound* in the partition lattice of E .

The following immediate property makes a link between comparable partitions and comparable substitutions.

Property 5 *Let P_1 and P_2 be two admissible partitions over the same set such that $P_1 \geq P_2$, with associated substitutions u_1 and u_2 respectively. Then there is a substitution u such that $u_2 = s \circ u_1$ (i.e., u_1 is “more general” than u_2).*

In the following definition of a piece-unifier, we assume that Q and R have disjoint sets of variables.

Definition 11 (Piece-Unifier, Separating Variable, Cutpoint) *A piece-unifier of Q with R is a triple $\mu = (Q', H', P_u)$, where $Q' \neq \emptyset$, $Q' \subseteq Q$, $H' \subseteq \text{head}(R)$ and P_u is a partition on $\text{terms}(Q') \cup \text{terms}(H')$ satisfying the three following conditions:*

1. P_u is admissible, i.e., no class in P_u contains two constants;
2. if a class in P_u contains an existential variable (from H') then the other terms in the class are non-separating variables from Q' ; we call separating variables from Q' , and note $\text{sep}(Q')$, the variables occurring in both Q' and $(Q \setminus Q')$: $\text{sep}(Q') = \text{vars}(Q') \cap \text{vars}(Q \setminus Q')$.
3. let u be a substitution associated with P_u obtained by selecting an element in each class, with priority given to constants; then $u(H') = u(Q')$.

We call *cutpoints*, and note $\text{cutp}(\mu)$, the variables from Q' that are not unified with existential variables from H' (i.e., they are unified with frontier variables or constants): $\text{cutp}(\mu) = \{x \in \text{vars}(Q') \mid u(x) \in \text{fr}(R) \cup \text{consts}(Q') \cup \text{consts}(H')\}$.

³Usually, the notation \leq is used to denote the relation “finer than”. We adopt the converse convention, which is more in line with substitutions and the \geq preorder on CQs.

Figure 3: Piece-unifier

Condition 2 in the piece-unifier definition ensures that a separating variable in Q' is necessarily a cutpoint. It follows that Q' is composed of pieces: indeed, an existential variable from H' is necessarily unified with a non-separating variable from Q' , say x , which ensures that all atoms from Q' in which x occurs are also part of Q' . Figure 5 illustrates these notions.

We provide below some examples of piece-unifiers.

Example 4 Let $R = q(x) \rightarrow p(x, y)$ and $Q = p(u, v) \wedge p(w, v) \wedge p(w, t) \wedge r(u, w)$. Let $H' = \{p(x, y)\}$. They are three piece-unifiers of Q with R :

$\mu_1 = (Q'_1, H', P_u^1)$ with $Q'_1 = \{p(u, v), p(w, v)\}$ and $P_u^1 = \{\{x, u, w\}, \{y, v\}\}$

$\mu_2 = (Q'_2, H', P_u^2)$ with $Q'_2 = \{p(w, t)\}$ and $P_u^2 = \{\{x, w\}, \{y, t\}\}$

$\mu_3 = (Q'_3, H', P_u^3)$ with $Q'_3 = \{p(u, v), p(w, v), p(w, t)\}$ and $P_u^3 = \{\{x, u, w\}, \{y, v, t\}\}$

Note that Q'_1 and Q'_2 are each composed of a single piece; $Q'_3 = Q'_1 \cup Q'_2$ and P_u^3 is the join of P_u^1 and P_u^2 .

In the previous example, R has an atomic head, thus a piece-unifier of Q' with R actually unifies the atoms from Q' and the head of R into a single atom. In the general case, a piece-unifier unifies Q' and a subset H' of $\text{head}(R)$ into a set of atoms, as illustrated by the next example.

Example 5 Let $R = q(x) \rightarrow p(x, y) \wedge p(y, z) \wedge p(z, t) \wedge r(y)$ and $Q = p(u, v) \wedge p(v, w) \wedge r(u)$. A piece-unifier of Q with R is $\mu_1 = (Q'_1, H'_1, P_u^1)$ with $Q'_1 = \{p(u, v), p(v, w)\}$, $H'_1 = \{p(x, y), p(y, z)\}$ and $P_u^1 = \{\{x, u\}, \{v, y\}, \{w, z\}\}$. Another piece-unifier is $\mu_2 = (Q'_2, H'_2, P_u^2)$ with $Q'_2 = Q$, $H'_2 = \{p(y, z), p(z, t), r(y)\}$ and $P_u^2 = \{\{u, y\}, \{v, z\}, \{w, t\}\}$.

Note that $\mu_3 = (Q'_3, H'_3, P_u^3)$ with $Q'_3 = \{p(u, v)\}$, $H'_3 = \{p(x, y)\}$ and $P_u^3 = \{\{x, u\}, \{v, y\}\}$ is not a piece-unifier because the second condition in the definition of piece-unifier is not fulfilled: v is a separating variable and is matched with the existential variable y .

Then, the notions of a one-step rewriting based on a piece-unifier and of a rewriting obtained by a sequence of one-step rewritings are defined in the natural way.

Definition 12 (One-step Piece-Rewriting) Given a piece-unifier $\mu = (Q', H', P_u)$ of Q with R , the one-step piece-rewriting of Q according to μ , denoted $\beta(Q, R, \mu)$, is the $BCQ \ u(\text{body}(R)) \cup u(Q \setminus Q')$, where u is a substitution associated with P_u .

We thus define inductively a k -step piece-rewriting as a $(k-1)$ -step piece rewriting of a one-step piece-rewriting. For any k , a k -step piece-rewriting of Q is a piece-rewriting of Q .

The next theorem states that piece-based rewriting is logically sound and complete.

Theorem 4 (basically [SM96]; see also [BLMS11]) *Let $\mathcal{K} = (F, \mathcal{R})$ be a KB and Q be a BCQ. Then $F, \mathcal{R} \models Q$ iff there is Q' a piece-rewriting of Q such that $Q' \geq F$.*

It follows from Theorem 4 that a sound and complete rewriting operator can be based on piece-unifiers: we call *piece-based rewriting operator*, the rewriting operator that, given Q and \mathcal{R} , outputs all the one-step piece-rewritings of Q according to a piece-unifier of Q with $R \in \mathcal{R}$. We denote it by $\beta(Q, \mathcal{R})$.

Actually, as detailed hereafter, only most general piece-unifiers are to be considered, since the other piece-unifiers produce more specific queries.

Definition 13 (Most General Piece-Unifier) *Given two piece-unifiers defined on the same subsets of a query and a rule head, $\mu_1 = (Q', H', P_u^1)$ and $\mu_2 = (Q', H', P_u^2)$, we say that μ_1 is more general than μ_2 (notation $\mu_1 \geq \mu_2$) if P_u^1 is finer than P_u^2 (i.e., $P_u^1 \geq P_u^2$). A piece-unifier $\mu = (Q', H', P_u)$ is called a most general piece-unifier if it is more general than all piece-unifiers on Q' and H' .*

Property 6 *Let μ_1 and μ_2 be two piece-unifiers with $\mu_1 \geq \mu_2$. Then μ_1 and μ_2 have the same pieces.*

Proof: μ_1 and μ_2 have the same pieces iff they have the same cutpoints. It holds that $cutp(\mu_1) \subseteq cutp(\mu_2)$ since every class from P_u^1 is included in a class from P_u^2 : hence a variable from Q' that is in the same class as a frontier variable or a constant in P_u^1 also is in P_u^2 . It remains to prove that $cutp(\mu_2) \subseteq cutp(\mu_1)$. Let x be a cutpoint of μ_2 and $P_u^2(x)$ be the class of x in P_u^2 . Since x is a cutpoint of μ_2 , there is a term t in $P_u^2(x)$ that is a constant or a frontier variable. Since $P_u^1 \geq P_u^2$, we know that $P_u^1(x) \subseteq P_u^2(x)$. Let t' be a term of H' from $P_u^1(x)$ (there is at least one term of H' and one term of Q' in each class since the partition is part of a unifier of H' and Q'). We are sure that t' is not an existential variable because $t' \in P_u^2(x)$ too and an existential variable cannot be in the same class as t (Condition 2 in the definition of a piece-unifier), so t' is a frontier variable or a constant, hence x is a cutpoint of μ_1 . \square

Property 7 *Let $\mu_1 = (Q', H', P_u^1)$ and $\mu_2 = (Q', H', P_u^2)$ be two piece-unifiers such that $\mu_1 \geq \mu_2$. Then $\beta(Q, R, \mu_1) \geq \beta(Q, R, \mu_2)$.*

Proof: Let u_1 (resp. u_2) be a substitution associated with P_u^1 (resp. P_u^2). Since $P_u^1 \geq P_u^2$, there is a substitution s such that $u_2 = s \circ u_1$. Then $\beta(Q, R, \mu_2) = u_2(\text{body}(R)) \cup u_2(Q \setminus Q') = (s \circ u_1)(\text{body}(R)) \cup (s \circ u_1)(Q \setminus Q') = (s \circ u_1)(\text{body}(R) \cup (Q \setminus Q')) = s(u_1(\text{body}(R) \cup (Q \setminus Q'))) = s(\beta(Q, R, \mu_1))$. s is thus a homomorphism from $\beta(Q, R, \mu_1)$ to $\beta(Q, R, \mu_2)$, hence $\beta(Q, R, \mu_1) \geq \beta(Q, R, \mu_2)$. \square

The following lemma expresses that the piece-based rewriting operator is prunable.

Lemma 3 *If $Q_1 \geq Q_2$ then for any piece-unifier μ_2 of Q_2 with R : either (i) $Q_1 \geq \beta(Q_2, R, \mu_2)$ or (ii) there is a piece-unifier μ_1 of Q_1 with R such that $\beta(Q_1, R, \mu_1) \geq \beta(Q_2, R, \mu_2)$.*

Proof: Let h be a homomorphism from Q_1 to Q_2 . Let $\mu_2 = (Q_2', H_2', P_u^2)$ be a piece-unifier of Q_2 with R , and let u_2 be a substitution associated with P_u^2 . We consider two cases:

- (i) If $h(Q_1) \subseteq (Q_2 \setminus Q'_2)$, then $u_2 \circ h$ is a homomorphism from Q_1 to $u_2(Q_2 \setminus Q'_2) \subseteq \beta(Q_2, R, \mu_2)$. Thus $Q_1 \geq \beta(Q_2, R, \mu_2)$.
- (ii) Otherwise, let Q'_1 be the non-empty subset of Q_1 mapped by h to Q'_2 , i.e., $h(Q'_1) \subseteq Q'_2$, and H'_1 be the subset of H'_2 matched by u_2 with $u_2(h(Q'_1))$, i.e., $u_2(H'_1) = u_2(h(Q'_1))$. Let P_u^1 be the partition on $term.s(H'_1) \cup term.s(Q'_1)$ such that two terms are in the same class of P_u^1 if these terms or their images by h are in the same class of P_u^2 (i.e., for a term t , we consider t if t is in Q'_1 , and $h(t)$ otherwise). By construction, (Q'_1, H'_1, P_u^1) is a piece-unifier of Q_1 with R . Indeed, P_u^1 fulfills all the conditions of the piece-unifier definition since P_u^2 fulfills them.

Let u_1 be a substitution associated with P_u^1 . For each class P of P_u^1 (resp. P_u^2), we call selected element the unique element t of P such that $u_1(t) = t$ (resp. $u_2(t) = t$). We build a substitution s from the selected elements of the classes in P_u^1 which are variables to the selected elements of the classes in P_u^2 as follows: for any class P of P_u^1 , let t be the selected element of P : if t is a variable of H'_1 then $s(t) = u_2(t)$, otherwise $s(t) = u_2(h(t))$ (t occurs in Q'_1). Note that for any term t in P_u^1 we have $s(u_1(t)) = u_2(h(t))$.

We build now a substitution h' from $vars(\beta(Q_1, R, \mu_1))$ to $terms(\beta(Q_2, R, \mu_2))$, by considering three cases according to the part of $\beta(Q_1, R, \mu_1)$ in which the variable occurs (in Q_1 but not in Q'_1 , in $body(R)$ but not in H'_1 , or in the remaining part corresponding to the images of $sep(Q'_1)$ by u_1):

1. if $x \in vars(Q_1) \setminus vars(Q'_1)$, $h'(x) = h(x)$;
2. if $x \in vars(body(R)) \setminus vars(H'_1)$, $h'(x) = u_2(x)$;
3. if $x \in u_1(sep(Q'_1))$ (or alternatively $x \in u_1(fr(R) \cap vars(H'_1))$), $h'(x) = s(x)$;

We conclude by showing that h' is a homomorphism from $\beta(Q_1, R, \mu_1) = u_1(body(R)) \cup u_1(Q_1 \setminus Q'_1)$ to $\beta(Q_2, R, \mu_2) = u_2(body(R)) \cup u_2(Q_2 \setminus Q'_2)$ with two points:

1. $h'(u_1(body(R))) = u_2(body(R))$. Indeed, for any variable x of $body(R)$:
 - either $x \in vars(body(R)) \setminus vars(H'_1)$, so $h'(u_1(x)) = h'(x) = u_2(x)$ (u_1 is a substitution from variables of $Q'_1 \cup H'_1$),
 - or $x \in fr(R) \cap vars(H'_1)$, so $h'(u_1(x)) = s(u_1(x)) = u_2(h(x)) = u_2(x)$ (h is a substitution from variables of Q_1).
2. $h'(u_1(Q_1 \setminus Q'_1)) \subseteq u_2(Q_2 \setminus Q'_2)$. We show that $h'(u_1(Q_1 \setminus Q'_1)) = u_2(h(Q_1 \setminus Q'_1))$ and since $h(Q_1 \setminus Q'_1) \subseteq Q_2 \setminus Q'_2$, we have $h'(u_1(Q_1 \setminus Q'_1)) \subseteq u_2(Q_2 \setminus Q'_2)$. To show that $h'(u_1(Q_1 \setminus Q'_1)) = u_2(h(Q_1 \setminus Q'_1))$, just see that for any variable x from $Q_1 \setminus Q'_1$:
 - either $x \in vars(Q'_1)$, then $h'(u_1(x)) = s(u_1(x)) = u_2(h(x))$
 - or $x \in vars(Q_1) \setminus vars(Q'_1)$, then $h'(u_1(x)) = h'(x) = h(x) = u_2(h(x))$ (u_1 is a substitution from variables of $Q'_1 \cup H'_1$ and u_2 is a substitution from variables of $Q'_2 \cup H'_2$ and $h(x) \notin vars(Q'_2 \cup H'_2)$).

□

We are now able to show that the piece-based rewriting operator fulfills all the desired properties introduced in section 4.

Theorem 5 *Piece-based rewriting operator is sound, complete and prunable; this property is still true if only most general piece-unifiers are considered.*

Proof: Soundness and completeness follow from Theorem 4. Prunability follows from Lemma 3. Thanks to Property 7, the proof remains true if most general piece-unifiers are considered. \square

6 Exploiting Single-Piece Unifiers

We are now interested in the efficient computation of piece-based rewritings. We identify several sources of combinatorial explosion in the computation of the piece-unifiers between a query and a rule:

1. The problem of deciding whether there is a piece-unifier of a given query Q with a given rule R is NP-complete in the general case. NP-hardness is easily obtained by considering the case of a rule with an empty frontier: then there is a piece-unifier between Q and R if and only if there is a homomorphism from Q to $H = \text{head}(R)$, which is an NP-complete problem, Q and H being any sets of atoms.
2. The number of most general piece-unifiers can be exponential in $|Q|$, even if the rule head H is restricted to a single atom. For instance, assume that each atom of Q unifies with H and forms its own piece; then there may be $2^{|Q|}$ piece-unifiers obtained by considering all subsets of Q .
3. The same atom in Q may belong to distinct pieces according to distinct unifiers, as illustrated by the next example.

Example 6 *Let $Q = r(u, v) \wedge q(v)$ and $R = p(x) \rightarrow r(x, y) \wedge r(y, x) \wedge q(y)$. Atom $r(u, v)$ belongs to two single-piece unifiers: $(\{r(u, v), q(v)\}, \{r(x, y), q(y)\}, \{\{u, x\}, \{v, y\}\})$ and $(\{r(u, v)\}, \{r(y, x)\}, \{\{u, y\}, \{v, x\}\})$. For an additional example, see Example 5, where $p(u, v)$ and $p(v, w)$ both belong to μ_1 and μ_2 .*

To cope with this complexity, one idea is to rely on *single-piece* unifiers, i.e., piece-unifiers of the form $(Q', -, -)$ where Q' is a single piece of Q . This section is devoted to the properties of rewriting operators exploiting this notion. Another idea is to focus on rules with an *atomic head*, which will be done in the next section. Atomic-head rules are often considered in the literature, specifically in logic programming or in deductive databases. Furthermore, any existential rule can be decomposed into an equivalent set of rules with atomic head by introducing a new predicate gathering the variables of the original head (e.g. [CGK08, BLMS09]). Hence, this restriction can be made without loss of expressivity. Considering atomic-head rules does not simplify the definition of a piece-unifier in itself, but its computation: there is now a unique way of associating any atom from Q with the head of a rule. Thus, deciding whether there is a piece-unifier of Q with a rule can be done in linear time with respect to the size of Q (which tames complexity source 1 in the above list) and each atom belongs to a single piece (see complexity source 3), thus the set of all single-piece unifiers of Q with a rule can be computed in polynomial time.

In this section, we show that the rewriting operator based on single-piece (most general) unifiers is sound and complete. However, perhaps surprisingly, it is not prunable, which prevents to use it in the generic algorithm. To recover prunability, we will

define the aggregation of single-piece unifiers, which provides us with a new rewriting operator, which has all the desired properties and generates less rewritings than the standard piece-unifier. Note however that this will not completely remove the second complexity source (i.e., the exponential number of unifiers to consider) since the number of aggregations of single-piece unifiers can still be exponential in the size of Q , even with atomic-head rules.

6.1 Single-Piece Based Operator

As expressed by the following theorem, (most general) single-piece unifiers provide a sound and complete operator.

Theorem 6 *Given a BCQ Q and a set of rules \mathcal{R} , the set of rewritings of Q obtained by considering exclusively most general single-piece unifiers is sound and complete.*

Proof: See Appendix. \square

The proof of this theorem is given in Appendix since it is not reused hereafter. Indeed, the restriction to single-piece unifiers is not compatible with selecting most general rewritings at each step, as done in Algorithm 1. We present below some examples that illustrate this incompatibility.

Example 7 (Basic example) *Let $Q = p(y, z) \wedge p(z, y)$ and $R = r(x, x) \rightarrow p(x, x)$. There are two single-piece unifiers of Q with R , $\mu_1 = (\{p(y, z)\}, \{p(x, x)\}, \{\{x, y, z\}\})$ and $\mu_2 = (\{p(z, y)\}, \{p(x, x)\}, \{\{x, y, z\}\})$, which yield the same rewriting, e.g. $Q_1 = r(x, x) \wedge p(x, x)$. There is also a two-piece unifier $\mu = (Q, \{p(x, x)\}, \{\{x, y, z\}\})$, which yields e.g. $Q' = r(x, x)$. A query equivalent to Q' can be obtained from Q_1 by a further single-piece unification. Now, assume that we restrict unifiers to single-piece unifiers and keep most general rewritings at each step. Since $Q \geq Q_1$, Q_1 is not kept, so Q' will never be generated, whereas it is incomparable with Q .*

Concerning the preceding example, one may argue that $u_1(Q)$ is redundant (and the same holds for $u_2(Q)$), and that the problem would be solved by computing $u_1(Q) \setminus u_1(Q')$ instead of $u_1(Q \setminus Q')$ and making $u_1(Q)$ non-redundant (i.e., equal to $p(x, x)$) before computing $u_1(Q) \setminus u_1(Q')$, which would then be empty. However, the problem goes deeper, as the next examples show it.

Example 8 (Ternary predicates) *Let $Q = r(u, v, w) \wedge r(w, t, u)$ and $R = p(x, y) \rightarrow r(x, y, x)$. Again, there are two single-piece unifiers of Q with R : $\mu_1 = (\{r(u, v, w)\}, \{r(x, y, x)\}, \{\{u, w, x\}, \{v, y\}\})$ and $\mu_2 = (\{r(w, t, u)\}, \{r(x, y, x)\}, \{\{u, w, x\}, \{t, y\}\})$. One obtains two rewritings more specific than Q , e.g. $Q_1 = p(x, y) \wedge r(x, v, x)$, and $Q_2 = p(x, y) \wedge r(x, t, x)$, which are isomorphic. There is also a two-piece unifier $(Q, \{r(x, y, x)\}, \{\{u, w, x\}, \{v, t, y\}\})$, which yields e.g. $p(x, y)$. If we remove Q_1 and Q_2 , no query equivalent to $p(x, y)$ can be generated.*

Example 9 (Very simple rule) *This example has two interesting characteristics: (1) it uses unary/binary predicates only (2) it uses a very simple rule expressible with any lightweight description logic, i.e., a linear existential rule where no variable appears twice in the head or the body. Let $Q = r(u, v) \wedge r(v, w) \wedge p(u, z) \wedge p(v, z) \wedge p(v, t) \wedge p(w, t) \wedge p_1(u) \wedge p_2(w)$ (see Figure 4) and $R = b(x) \rightarrow p(x, y)$. Note that Q is not redundant. There are two single-piece unifiers of Q with R , say μ_1 and μ_2 , with*

Figure 4: The queries in Example 9

pieces $Q'_1 = \{p(u, z), p(v, z)\}$ and $Q'_2 = \{p(v, t), p(w, t)\}$ respectively. The obtained queries are pictured in Figure 4. These queries are both more specific than Q . The removal would prevent the generation of a query equivalent to $r(x, x) \wedge p_1(x) \wedge p_2(x) \wedge b(x)$, which could be generated from Q with a two-piece unifier.

Property 8 *The single-piece-based operator is not prunable.*

Proof: Follows from the above examples. \square

By Theorem 5 and Property 13, one can show that the conclusion of Lemma 1 is valid for single-piece unifiers, even though they are not prunable. This justifies that Lemma 1 is not enough to prove the correctness of Algorithm 1. However, single-piece unifiers can still be used as an algorithmic brick to compute more complex piece-unifiers, as shown in the next subsection.

6.2 Aggregated-Piece Based Operator

We first explain the ideas that underline aggregated single-piece unifiers. Let us consider the set of single-piece unifiers naturally associated with a piece-unifier μ . If we apply successively each of these underlying single-piece unifiers, we may obtain a CQ strictly more general than $\beta(Q, R, \mu)$, as illustrated in the next example.

Example 10 *Let $R = p(x, y) \rightarrow q(x, y)$ and $Q = q(u, v) \wedge r(v, w) \wedge q(t, w)$. Let $\mu = (Q', H', P_u)$ be a piece-unifier of Q with R with $Q' = \{q(u, v), q(t, w)\}$, $H' = \{q(x, y)\}$ and $P_u = \{\{u, t, x\}, \{v, w, y\}\}$. $\beta(Q, R, \mu) = p(x, y) \wedge r(y, y)$. Q' has two pieces w.r.t. μ : $P_1 = \{q(u, v)\}$ and $P_2 = \{q(t, w)\}$. If we successively computing the rewritings with the underlying single-piece unifiers μ_{P_1} and μ_{P_2} , we obtain $\beta(\beta(Q, R, \mu_{P_1}), R, \mu_{P_2}) = \beta(p(x, y) \wedge r(y, w) \wedge q(t, w), R, \mu_{P_2}) = p(x, y) \wedge r(y, y') \wedge p(x', y')$, which is strictly more general than $\beta(Q, R, \mu)$.*

Given a set \mathcal{U} of “compatible” single-piece unifiers of a query Q with a rule (the notion of “compatible” will be formally defined below), we can thus distinguish between the usual piece-unifier performed on the union of the pieces from the unifiers in \mathcal{U} and an “aggregated unifier” that would correspond to a sequence of applications of the single piece-unifiers in \mathcal{U} . This latter unifier is more interesting than the piece-unifier because, as illustrated by Example 10, it avoids generating some rewritings which are too specific. We will thus rely on the aggregation of single-piece unifiers to recover prunability.

Note that, in this paper, we combine single-piece unifiers of the *same* rule whereas in [KLMT13] we consider the possibility of combining unifiers of distinct rules (and

thus compute rewritings from distinct rules in a single step). We keep here the definitions introduced in [KLMT13], while pointing out that, in the context of this paper, the rules $R_1 \dots R_k$ are necessarily copies of the same rule R .

Definition 14 (Compatible Piece-Unifiers) Let $\mathcal{U} = \{\mu_1 = (Q'_1, H'_1, P_1) \dots \mu_k = (Q'_k, H'_k, P_k)\}$ be a set of piece-unifiers of Q with rules $R_1 \dots R_k$ respectively, where all R_i have disjoint sets of variables (hence, for all $1 \leq i, j \leq k, i \neq j, \text{vars}(H'_i) \cap \text{vars}(H'_j) = \emptyset$). \mathcal{U} is said to be compatible if (1) all Q'_i and Q'_j are pairwise disjoint; (2) the join of $P_1 \dots P_k$ is admissible.

Definition 15 (Aggregated unifier) Let $\mathcal{U} = \{\mu_1 = (Q'_1, H'_1, P_1), \dots, \mu_k = (Q'_k, H'_k, P_k)\}$ be a compatible set of piece-unifiers of Q with rules $R_1 \dots R_k$. An aggregated unifier of Q with $R_1 \dots R_k$ w.r.t. \mathcal{U} is $\mu = (Q', H', P)$ where: (1) $Q' = Q'_1 \cup \dots \cup Q'_k$; (2) $H' = H'_1 \cup \dots \cup H'_k$; (3) P is the join of $P_1 \dots P_k$. It is said to be single-piece if all the piece-unifiers of \mathcal{U} are single-piece. It is said to be most general if all the piece-unifiers of \mathcal{U} are most general.

Definition 16 (Aggregation of a set of rules) The aggregation of a set of rules $\mathcal{R} = \{R_1 \dots R_k\}$, denoted by $R_1 \diamond \dots \diamond R_k$, is the rule $\text{body}(R_1) \wedge \dots \wedge \text{body}(R_k) \rightarrow \text{head}(R_1) \wedge \dots \wedge \text{head}(R_k)$, where it is assumed that all rules have disjoint sets of variables.

Property 9 Let Q be a BCQ and $\mathcal{U} = \{\mu_1 = (Q'_1, H'_1, P_1) \dots \mu_k = (Q'_k, H'_k, P_k)\}$ be a compatible set of piece-unifiers of Q with $R_1 \dots R_k$. Then the aggregated unifier of \mathcal{U} is a piece-unifier of Q with the aggregation of $\{R_1 \dots R_k\}$.

Proof: We show that the aggregated unifier $\mu = (Q', H', P_u)$ of \mathcal{U} satisfies the conditions of the definition of a piece-unifier. Condition 1 is fulfilled since by definition of compatibility, the join of $P_1 \dots P_k$ is admissible. Condition 2 is satisfied too, because since $P_1 \dots P_k$ satisfy it, so does their join. Indeed, if a class contains an existential variable, it cannot be merged with another by aggregation because its other terms are non-separating variables, hence do not appear in other classes. Concerning the last condition, for all $1 \leq i \leq k$ we have $u_i(H'_i) = u_i(Q'_i)$ where u_i is a substitution associated with P_i . Since $Q' = \bigcup_{i=1}^k Q'_i$ and $H' = \bigcup_{i=1}^k H'_i$ we are sure that for any substitution u associated with P_u we have $u(H') = u(Q')$. \square

The rewriting associated with an aggregated unifier μ can thus be defined as $\beta(Q, R_1 \diamond \dots \diamond R_k, \mu)$. It is equivalent to the rewriting obtained by applying the single-piece unifiers one after the other.

Example 11 Consider again Example 10. Let $R' = p(x', y') \rightarrow q(x', y')$ be a copy of R . Then the aggregation $R \diamond R'$ is the rule $p(x, y) \wedge p(x', y') \rightarrow q(x, y) \wedge q(x', y')$. Let $\mathcal{U} = \{\mu_{P_1}, \mu_{P_2}\}$ where $\mu_{P_1} = (\{q(u, v)\}, \{q(x, y)\}, \{\{u, x\}, \{v, y\}\})$ and $\mu_{P_2} = (\{q(t, w)\}, \{q(x', y')\}, \{\{t, x'\}, \{w, y'\}\})$. The aggregated unifier of Q with R, R' w.r.t. \mathcal{U} is $(\{q(u, v), q(t, w)\}, \{q(x, y), q(x', y')\}, \{\{u, x\}, \{v, y\}, \{t, x'\}, \{w, y'\}\})$. The associated rewriting of Q is $p(x, y) \wedge r(y, y') \wedge p(x', y')$.

Note that, if we assumed, in the definition of an aggregated unifier, that $R_1 = \dots R_k = R$ (and in particular have the same variables), then the aggregated unifier would be the usual piece-unifier, and the aggregation of $R_1 \dots R_k$ would be exactly R after removal of duplicate atoms. In other words, to build a standard piece-unifier of Q with R we consider partitions of $\text{terms}(Q) \cup \text{terms}(\text{head}(R))$, while in the aggregation

operation we consider $terms(Q) \cup \bigcup_{i=1}^k terms(head(R_i))$, where k is the number of single-piece unifiers of Q with R and each R_i is safely renamed from R .

The next property shows that from any piece-unifier μ , one can build a most general single-piece aggregated unifier, which produces a rewriting more general than the one produced by μ .

Property 10 *For any piece-unifier μ of Q with R , there is a most general single-piece aggregated unifier μ_\diamond of Q with $R_1 \dots R_k$ copies of R such that $\beta(Q, R_1 \diamond \dots \diamond R_k, \mu_\diamond) \geq \beta(Q, R, \mu)$.*

Proof: Let Q'_1, \dots, Q'_k be the pieces of Q' according to $\mu = (Q', H', P_u)$ and let u be a substitution associated to P_u . Let $R_1 \dots R_k$ be safely renamed copies of R . Let h_i denote the variable renaming used to produce R_i from R . Let $\mathcal{U} = \{\mu_1 = (Q'_1, H'_1, P_u^1), \dots, \mu_k = (Q'_k, H'_k, P_u^k)\}$ be a set of piece-unifiers of Q with R_1, \dots, R_k built as follows for all i :

- H'_i is the image by h_i of the subset of H' unified by u with Q'_i
- let $h_i(P_u)$ be the partition built from P_u by replacing each $x \in vars(H')$ by $h_i(x)$; then P_u^i is obtained from $h_i(P_u)$ by (1) restricting it to the terms of Q'_i and H'_i (2) refining it as much as possible while keeping the property that $u_i(H'_i) = u_i(Q'_i)$, where u_i is a substitution associated with the partition.

For any $\mu_i = (Q'_i, H'_i, P_u^i)$ we immediately check that:

1. μ_i is a most general piece-unifier.
2. μ_i is a single-piece unifier.
3. $\forall \mu_j \in \mathcal{U}, \mu_i \neq \mu_j, \mu_j$ and μ_i are compatible.

Let $\mu_\diamond = (Q'_\diamond, H'_\diamond, P_u^\diamond)$ be the aggregated unifier of Q with R_1, \dots, R_k w.r.t. \mathcal{U} . Note that $Q'_\diamond = Q'$. The above properties fulfilled by any μ_i from \mathcal{U} ensure that μ_\diamond is a most general single-piece aggregated unifier.

We note $R_\diamond = R_1 \diamond \dots \diamond R_k$. It remains to prove that $\beta(Q, R_\diamond, \mu_\diamond) \geq \beta(Q, R, \mu)$. Let u_\diamond be a substitution associated with P_u^\diamond . For each class P of P_u (resp. P_u^\diamond), we call selected element the unique element t of P such that $u(t) = t$ (resp. $u_\diamond(t) = t$).

We build a substitution s from the selected elements in P_u^\diamond which are variables to the selected elements in P_u as follows: for any class P of P_u^\diamond , let t be the selected element of P : if t is a variable of Q' then $s(t) = u(t)$; else t is a variable of a H'_i : then $s(t) = u(h_i^{-1}(t))$. Note that for any term t in P_u^\diamond , there is a variable renaming h_i such that $s(u_\diamond(t)) = u(h_i^{-1}(t))$ (if t is a constant or a variable from $vars(Q)$ then any h_i can be chosen).

We build now a substitution h from $vars(\beta(Q, R_\diamond, \mu_\diamond))$ to $terms(\beta(Q, R, \mu))$, by considering three cases according to which part of $\beta(Q, R_\diamond, \mu_\diamond)$ the variable occurs (in Q but not in Q' , in $body(R_i)$ but not in H'_i , or in the remaining part corresponding to the images of $sep(Q')$ by u_\diamond):

1. if $x \in vars(Q) \setminus vars(Q')$, $h(x) = x$;
2. if $x \in vars(body(R_i)) \setminus vars(H'_i)$, $h(x) = h_i^{-1}(x)$;
3. if $x \in u_\diamond(sep(Q'))$ (or alternatively $x \in u_\diamond(fr(R_\diamond) \cap vars(H'_\diamond))$), $h(x) = s(x)$;

We conclude by showing that h is a homomorphism from $\beta(Q, R_\diamond, \mu_\diamond) = u_\diamond(\text{body}(R_1) \cup \dots \cup \text{body}(R_k)) \cup u_\diamond(Q \setminus Q')$ to $\beta(Q, R, \mu) = u(\text{body}(R)) \cup u(Q \setminus Q')$ with two points:

1. for all i , $h(u_\diamond(\text{body}(R_i))) = u(\text{body}(R))$. Indeed, for any variable $x \in \text{vars}(\text{body}(R_i))$:
 - either $x \in \text{vars}(\text{body}(R_i)) \setminus \text{vars}(H'_i)$, so $h(u_\diamond(x)) = h(x) = h_i^{-1}(x) = u(h_i^{-1}(x))$ (u does not substitute the variables in $\text{vars}(\text{body}(R)) \setminus \text{vars}(H')$),
 - or $x \in \text{fr}(R_i) \cap \text{vars}(H'_i)$, so $h(u_\diamond(x)) = s(u_\diamond(x)) = u(h_i^{-1}(x))$;
2. $h(u_\diamond(Q \setminus Q')) = u(Q \setminus Q')$. Indeed, for any variable $x \in \text{vars}(Q \setminus Q')$:
 - either $x \in \text{vars}(Q')$, then $h(u_\diamond(x)) = s(u_\diamond(x)) = u(h_i^{-1}(x)) = u(x)$ (h_i^{-1} does not substitute the variables in Q),
 - or $x \in \text{vars}(Q) \setminus \text{vars}(Q')$, then $h(u_\diamond(x)) = h(x) = x = u(x)$ (u_\diamond and u do not substitute the variables in $\text{vars}(Q) \setminus \text{vars}(Q')$).

□

We call *single-piece aggregator* the rewriting operator that computes the set of one-step rewritings of a query Q by considering all the most general single-piece aggregated unifiers of Q .

Theorem 7 *The single-piece aggregator is sound, complete and prunable.*

Proof: Soundness comes from Property 9 and from the fact that for any set of rules \mathcal{R} , let the rule R be its aggregation, one has $\mathcal{R} \models R$. Completeness and prunability rely on the fact that the piece-based rewriting operator fulfills these properties and the fact that for any queries Q and Q' and any rule R , if $Q' = \beta(Q, R, \mu)$, where μ is a piece-unifier, then the query Q'' obtained with the single-piece aggregator corresponding to μ is more general than Q' , as expressed by Property 10. □

7 Implementation and Experiments

As explained in Section 6, we now restrict our focus to rules with an *atomic head*. We first detail algorithms for computing all the most general single-piece unifiers of a query Q with a rule R and explain how we use them to compute all single-piece aggregators. Then we report first experiments.

7.1 Computing single-piece unifiers and their aggregation

When a rule R has an atomic head, it holds that every atom in Q participates in *at most one* most general single-piece unifier of Q with R (up to bijective variable renaming). This is a corollary of the next property.

Property 11 *Let R be an atomic-head rule and Q be a BCQ. For all atom $a \in Q$, there is at most one $Q' \subseteq Q$ such that $a \in Q'$ and Q' is a piece for a piece-unifier of Q with R .*

Proof: We prove by contradiction that two single-piece unifiers cannot share an atom of Q . Assume there are $Q'_1 \subseteq Q$ and $Q'_2 \subseteq Q$ such that $Q'_1 \neq Q'_2$ and $Q'_1 \cap Q'_2 \neq \emptyset$, and $\mu_1 = (Q'_1, H, P_u^1)$ and $\mu_2 = (Q'_2, H, P_u^2)$ two single-piece-unifiers of Q with R ,

with $H = \text{head}(R)$. Since $Q'_1 \neq Q'_2$, one has $Q'_1 \setminus Q'_2 \neq \emptyset$ or $Q'_2 \setminus Q'_1 \neq \emptyset$. Assume $Q'_1 \setminus Q'_2 \neq \emptyset$. Let $A = Q'_1 \cap Q'_2$ and $B = Q'_1 \setminus A$. There is at least one variable $x \in \text{vars}(A) \cap \text{vars}(B)$ such that there is an existential variable e of $\text{head}(R)$ in the class of P_u^1 containing x (otherwise μ_1 has more than one piece). Since H is atomic, there is a unique way of associating any atom with H , thus the class of P_u^2 containing x contains also e . It follows that Q'_2 is not a piece since one atom of A and one atom of B share x unified with an existential variable in μ_2 while A is included in Q'_2 and B is not. \square

To compute most general single-piece unifiers, we first introduce the notion of the unification of a set of atoms with the head of a rule. This notion is an adaptation of the classical logical unification that takes existential variables into account. To define a piece-unifier, the set of atoms has to satisfy an additional constraint on its separating variables.

Definition 17 (Partition by Position) *Let A be a set of atoms with the same predicate p . The partition by position associated with A , denoted by $P_p(A)$, is the partition on $\text{terms}(A)$ such that two terms of A appearing in the same position i ($1 \leq i \leq \text{arity}(p)$) are in the same class of $P_p(A)$.*

Definition 18 (Unifiability) *Let R be an atomic head rule and let A be a set of atoms with same predicate p as $\text{head}(R)$. A is unifiable with R if no class of $P_p(A \cup \text{head}(R))$ contains two constants, or contains two existential variables of R , or contains a constant and an existential variable of R , or contains an existential variable of R and a frontier variable of R .*

Definition 19 (Sticky Variables) *Let Q be a BCQ, R be an atomic head rule and Q' be a subset of atoms in Q with the same predicate p as $\text{head}(R)$. The sticky variables of Q' with respect to Q and R , denoted by $\text{sticky}(Q')$, are the separating variables of Q' that occur in a class of $P_p(Q' \cup \text{head}(R))$ containing an existential variable of R .*

The following property follows from the definitions:

Property 12 *Let Q be a BCQ, R be an atomic head rule, and Q' a subset of atoms in Q with the same predicate p as $\text{head}(R)$. Then $\mu = (Q', \text{head}(R), P_p(Q' \cup \text{head}(R)))$ is a piece-unifier of Q with R iff Q' is unifiable with $\text{head}(R)$ and $\text{sticky}(Q') = \emptyset$.*

The fact that an atom from Q participates in at most one most general single-piece unifier suggests an incremental method to compute these unifiers. Assume that the head of R has predicate p . We start from each atom $a \in Q$ with predicate p and compute the subset of atoms from Q that would necessarily belong to the same piece as a ; more precisely, at each step, we build Q' such that Q' and $\text{head}(R)$ can be unified, then check if $\text{sticky}(Q') = \emptyset$. If there is a piece-unifier of Q' built in this way with $\text{head}(R)$, all atoms in Q' can be removed from Q for the search of other single-piece unifiers; otherwise, a is removed from Q for the search of other single-piece unifiers but the other atoms in Q' still have to be taken into account. Note that in both cases, the notion of separating variables is still relative to the original Q .

Example 12 *Let $R = q(x) \rightarrow p(x, y)$ and $Q = p(u, v) \wedge p(v, t)$. Let us start from $p(u, v)$: this atom is unifiable with $\text{head}(R)$ and $p(v, t)$ necessarily belongs to the same piece-unifier (if any) because $v \in \text{sticky}(\{p(u, v)\})$ (v is in the same class that the existential variable y); however, $\{p(u, v), p(v, t)\}$ is not unifiable with $\text{head}(R)$ because, since v occurs at the first and at the second position of a p atom, x and y should*

be unified, which is not possible since y is an existential variable; thus $p(u, v)$ does not belong to any piece-unifier with R . However, $p(v, t)$ still needs to be considered. Let us start from it: $p(v, t)$ is unifiable with $\text{head}(R)$ and forms its own piece because $\text{sticky}(\{p(v, t)\})$ is empty (t is in the same class that the existential variable y but is not shared with another atom). There is thus one (most general) piece-unifier of Q with R , namely $(\{p(v, t)\}, \{p(x, y)\}, \{\{v, x\}, \{t, y\}\})$.

More precisely, Algorithm 2 first builds the subset A of atoms in Q with the same predicate as $\text{head}(R)$. While A has not been emptied, it initializes a set Q' by picking an atom a in A , then repeats the following steps:

1. check if Q' is unifiable with $\text{head}(R)$; else, the attempt with a fails;
2. check if $\text{sticky}(Q') = \emptyset$; if so, it is a single-piece unifier and all the atoms in Q' are removed from A ;
3. otherwise, the algorithm tries to extend Q' with all the atoms in Q containing a variable from $\text{sticky}(Q')$; if these atoms are in A , Q' can grow, otherwise the attempt with a fails.

Algorithm 2: Computation of all most general single-piece unifiers

Data: a CQ Q and an atomic-head rule R

Result: the set of most general single-piece unifiers of Q with R

begin

$U \leftarrow \emptyset$; // resulting set

$A \leftarrow \{a \in Q \mid \text{predicate}(a) = \text{predicate}(\text{head}(R))\}$;

while $A \neq \emptyset$ **do**

$a \leftarrow$ choose an atom in A ;

$Q' \leftarrow \{a\}$;

while $Q' \subseteq A$ and $\text{unifiable}(Q', \text{head}(R))$ and $\text{sticky}(Q') \neq \emptyset$ **do**

$Q' \leftarrow Q' \cup \{a' \in Q \mid a' \text{ contains a variable in } \text{sticky}(Q')\}$;

if $Q' \subseteq A$ and $\text{unifiable}(Q', \text{head}(R))$ **then**

$U \leftarrow U \cup \{(Q', \text{head}(R), P_p(Q' \cup \text{head}(R)))\}$;

$A \leftarrow A \setminus Q'$

else

$A \leftarrow A \setminus \{a\}$

return U

Now, to compute the set of single-piece aggregators of Q with R , we proceed as follows:

1. Compute all (most general) single-piece unifiers of Q with R :
 $U_1 = \{\mu_1, \dots, \mu_k\}$;
2. For i from 2 to the greatest possible rank (as long as U_i is not empty): let U_i be the set of all i -unifiers obtained by aggregating an $i - 1$ -unifier from U_{i-1} and a single-piece unifier from U_1 .
3. Return the union of all the U_i obtained.

7.2 Experiments and Perspectives

The generic breadth-first algorithm, instantiated with the rewriting operator described in the preceding section, has been implemented in Java. First experiments were led on sets of existential rules obtained by translation from ontologies expressed in the description logic DL-Lite \mathcal{R} and developed in several research projects, namely ADOLINA (A), STOCKEXCHANGE (S), UNIVERSITY (U) and VICODI (V). See [GOP11] for more details. The obtained rules have atomic head and body, which corresponds to the linear Datalog \pm fragment. The associated queries were generated by the tool Sygenia [ISG12]. Sygenia provided us with 114, 185, 81 and 102 queries for ontologies A, S, U and V respectively. In [KLMT12] we compared with other systems concerning the size of the output and pointed out that none of the existing systems output a complete set of rewritings. However, beside the fact that these systems have evolved since then, one can argue that the size of the rewriting set should not be a decisive criterion (indeed, assuming that the systems are sound and complete, a minimal rewriting set can be obtained by selecting most general elements, see Theorem 1). Therefore, other criteria have to be taken into account, such as the running time or the total number of BCQs built during the rewriting process.

Table 1 presents for each ontology the total number of generated rewritings, i.e., the sum of the number of generated BCQs for all the queries associated with a given ontology (*# generated* column). This number can be compared with the total number of output rewritings, i.e., the sum of the cardinalities of the final output sets for all the queries associated with a given ontology (*# output* column). The generated rewritings are all the rewritings built during the rewriting process (excluding the initial query and possibly including some multi-occurrences of the same rewritings). Since we remove the subsumed rewritings at each step of the breadth-first algorithm, only some of the generated rewritings at a given step are explored at the next step. We can see that the number of generated queries can be huge with respect to the size of the output, specially for Ontology A.

Concerning the running time, our implementation is yet far from being optimized. Moreover, our system is able to process any kind of existential rules, which involves complex mechanisms. Much time could be saved by processing specific kinds of rules in a specific way. In particular, a large part of available ontologies is actually composed of concept and role hierarchies. For instance, 64%, 31%, 47% and 90% of the rules in ontologies A, S, U and V respectively, express atomic concept or atomic role inclusions. By simply processing these sets of rules as preorders, we can dramatically decrease the running time and the number of generated queries. First experiments with ontology A show that the running time is decreased by a factor of 74 approximatively, and the number of generated queries is divided by 37.

Further work includes processing specific kinds of rules in a specific way while keeping a system able to process any set of existential rules. Other optimizations could be implemented such as exploiting dependencies between rules to select the rules to be considered at each step. Moreover, the form of the considered output itself, i.e., a union of conjunctive queries, leads to combinatorial explosion. Considering semi-conjunctive queries instead of conjunctive queries as in [Tho13] can save much with respect to both the running time and the size of the output, without compromising the efficiency of query evaluation; to generate semi-conjunctive queries, the piece-based rewriting operator is combined with query factorization techniques. Finally, further experiments should be performed on more complex ontologies. However, even if slightly more complex ontologies could be obtained by translation from description logics, real-world

rule base	# output	# generated
A	3209	146 523
S	557	6515
U	486	2122
V	2694	5318

Table 1: Generated Queries with the Single-Piece Aggregator

ontologies that would take advantage of the expressiveness of existential rules, as well as associated queries, are currently lacking.

Acknowledgments. We thank Giorgio Orsi for providing us with rule versions of the ontologies. This work was partially funded by the ANR project PAGODA (ANR-12-JS02-007-01).

Appendix: Proof of Theorem 6

To prove the completeness of the single-piece based operator, we first prove the following property:

Property 13 *For any piece-unifier μ of Q with R , there is a sequence of rewritings of Q with R using exclusively most general single-piece unifiers and leading to a BCQ Q^s such that $Q^s \geq \beta(Q, R, \mu)$.*

Proof: We first introduce some notations. Given a partition P and x a term occurring in P , $P(x)$ is the class of P that contains x . Let P and P' be two partitions such that the terms of P' are included in the terms of P and any class of P' is included in a class of P : then we say that P' is a subpart of P (note that if P' and P are defined on the same set, it means that P' is finer than P)

Let P_{c_1}, \dots, P_{c_n} be the pieces of Q' according to $\mu = (Q', H', P_u)$ and let u be a substitution associated to P_u . Let $Q_0 = Q, Q_1, \dots, Q_n = Q^s$ be a sequence of rewritings of Q built as follows: for $1 \leq i \leq n$, $Q_i = \beta(Q_{i-1}, R_i, \mu_i)$ where $\mu_i = (Q'_i, H'_i, P_u^i)$ and u_i is a substitution associated with P_u^i with:

- R_i is a safely renamed copy of R by a variable renaming h_i .
- H'_i is the image by h_i of the subset of H' unified by u with P_{c_i}
- P_u^i is obtained from partition $h_i(P_u)$ (built from P_u by applying h_i) by (1) restricting it to the terms of Q'_i and H'_i (2) refining it as much as possible while keeping the property that it is associated with a unifier of H'_i and Q'_i . Note that P_u^i is a subpart of $h_i(P_u)$.
- Let $u_i^\circ = u_i \circ u_{i-1} \circ \dots \circ u_1$. Let $P_u^{i\circ}$ be the partition assigned to u_i° . We know that $P_u^{i\circ}$ is the join of P_u^1, \dots, P_u^i , thus $P_u^{i\circ}$ is a subpart of P_u^h , the join of the $h_i(P_u)$ for $1 \leq i \leq n$. Indeed, for each i , P_u^i is a subpart of $h_i(P_u)$ and the following property is easily checked: let s_1 and s_2 be substitutions with *disjoint* domains, and P_s^1, P_s^2 be their associated partitions; then, the partition assigned to $s_1 \circ s_2$ (and to $s_2 \circ s_1$) is exactly the join of P_s^1 and P_s^2 .
- $Q'_1 = P_{c_1}$ and for $i > 1$, $Q'_i = u_{i-1}^\circ(P_{c_i})$. We ensure the property that $\forall i, u_{i-1}^\circ(P_{c_i}) \cap u_{i-1}^\circ(Q \setminus Q') = \emptyset$. If $u_{i-1}^\circ(P_{c_i}) \cap u_{i-1}^\circ(Q \setminus Q') \neq \emptyset$, we remove μ_i from the sequence because it is useless since $u_{i-1}^\circ(P_{c_i}) \subseteq u_{i-1}^\circ(Q \setminus Q')$. Indeed, let $a \in u_{i-1}^\circ(P_{c_i}) \cap u_{i-1}^\circ(Q \setminus Q')$, there are $b \in P_{c_i}$ and $b' \in Q \setminus Q'$, $b \neq b'$ such that $u_{i-1}^\circ(b) = u_{i-1}^\circ(b') = a$, so $\text{terms}(b) \subseteq \text{sep}(P_{c_i})$, so $\{b\}$ is a piece, so $P_{c_i} = \{b\}$ and then $u_{i-1}^\circ(P_{c_i}) = \{a\} \subseteq u_{i-1}^\circ(Q \setminus Q')$. For similar reasons, we ensure the property that $\forall i, \forall j > i, u_{i-1}^\circ(P_{c_i}) \cap u_{i-1}^\circ(P_{c_j}) = \emptyset$.

We now show that:

1. μ_i is a piece-unifier
2. μ_i is a most general piece-unifier
3. μ_i is a single-piece unifier

For the first point:

- $Q'_i \subseteq Q_{i-1}$ since $\forall i, u_{i-1}^\circ(P_{c_i}) \cap u_{i-1}^\circ(Q \setminus Q') = \emptyset$ and $\forall i, \forall j > i, u_{i-1}^\circ(P_{c_i}) \cap u_{i-1}^\circ(P_{c_j}) = \emptyset$

- $H'_i \subseteq \text{head}(R_i)$ by construction.
- P_u^i satisfies the conditions of a piece-unifier because P_u satisfies them and P_u^i is a subpart of $h_i(P_u)$.

For the second point, since P_u^i is the finest partition associated with a piece-unifier of H'_i and Q'_i , we are sure that μ_i is a most general piece-unifier.

For the third point, note that each atom of Q'_i corresponds to at least one atom of PC_i . Thus if PC_i is composed of a unique atom, so is H'_i which thus forms a single-piece. Otherwise, PC_i is a single-piece from more than one atom; each atom a of PC_i contains a variable x such that $P_u(x)$ contains an existential variable y which comes from the subset of H' unified by u with PC_i . Thus the corresponding atom $u_{i-1}^\circ(a)$ in Q'_i is such that $P_u^i(u_{i-1}^\circ(x))$ contains the existential variable $h_i(y)$. So Q'_i forms a single piece.

At the end of the sequence, $Q_n \subseteq u_n^\circ(Q \setminus Q') \cup \bigcup_{j \in 1..n} (u_n(\dots u_j(\text{body}(R_j))))$ and the terms of $P_u^{n\circ}$ are the same as the terms of P_u^h . Since $P_u^{n\circ}$ is a subpart of P_u^h , we can say that $P_u^{n\circ}$ is finer than P_u^h so, there is a substitution s such that $u^h = s \circ u_n^\circ$ and $s(u_n^\circ(Q \setminus Q')) = u^h(Q \setminus Q')$. Let h be the substitution obtained by making the union of the inverses of the h_i , then $h(u^h(Q \setminus Q')) = u(Q \setminus Q')$, so $h \circ s$ is a homomorphism from $u_n^\circ(Q \setminus Q')$ to $u(Q \setminus Q')$. Then we can prove that for all j , $1 \leq j \leq n$, $h(s(u_n(\dots u_j(\text{body}(R_j)))) = u(\text{body}(R))$. Indeed, $u_n(\dots u_j(\text{body}(R_j))) = u_n(\dots u_1(\text{body}(R_j)))$ since the terms of $\text{body}(R_j)$ do not appear in u_i ($i < j$).

To conclude the proof, we have $h(s(Q_n)) \subseteq u(\text{body}(R)) \cup u(Q \setminus Q') = \beta(Q, \mu, R)$, hence $h \circ s$ is a homomorphism from Q_n to $\beta(Q, \mu, R)$, thus $Q_n \geq \beta(Q, \mu, R)$. \square

Theorem 6 *Given a BCQ Q and a set of rules \mathcal{R} , the set of rewritings of Q obtained by considering exclusively most general single-piece unifiers is sound and complete.*

Proof: Soundness holds trivially since a single-piece unifier is a piece-unifier.

For completeness, thanks to Theorem 4, we just have to show by induction on k , the length of the rewriting sequence leading from Q to a k -piece-rewriting of Q , that: for any k -piece-rewriting Q^r of Q , there exists Q^s a piece-rewriting of Q obtained by using exclusively most general single-piece unifiers such that $Q^s \geq Q^r$.

For $k = 0$ the property is trivially satisfied.

For $k \geq 1$, one has $Q^r = \beta(Q^{r'}, R, \mu)$, with $Q^{r'}$ being a piece-rewriting of Q obtained by a piece-rewriting sequence of length $k - 1$. By induction hypothesis, there exists $Q^{s'}$ a piece-rewriting of Q obtained by using exclusively single-piece unifiers such that $Q^{s'} \geq Q^{r'}$. By Lemma 3, either $Q^{s'} \geq Q^r$, or there is a piece-unifier μ' of $Q^{s'}$ with R such that $\beta(Q^{s'}, R, \mu') \geq Q^r$. In this latter case, thanks to Property 13, there is a sequence of rewritings of $Q^{s'}$ with R using only single-piece unifiers and leading to a CQ Q^s such that $Q^s \geq \beta(Q^{s'}, R, \mu')$. \square
