^a Research Institute for Artificial Intelligence "Mihai Drăgănescu", Romanian Academy, Romania E-mail: vasile@racai.ro

Abstract. LegalNERo is a manually annotated corpus for named entity recognition in the Romanian legal domain. It provides gold annotations for organizations, locations, persons, time expressions and legal resources mentioned in legal documents. Furthermore, GeoNames identifiers are provided. The resource is available in multiple formats, including span-based, token-based and RDF. The Linked Open Data version is available for both download and querying using SPARQL.

Keywords: Named entity recognition, Linguistic linked data, Romanian language, Corpus

1. Introduction

Named entity recognition (NER) is the task of identifying named entities (NE) in text [45], such as persons, locations, organizations, and proteins. Starting in 1995, within the MUC-6 conference [14], there have been periodic tasks on various aspects of NER. For example, for the CoNLL-2003 shared task [40], NEs were considered "phrases that contain the names of persons, organizations and locations". In this context, in the biomedical domain, a number of works have addressed entities such as genes, proteins, diseases [17], cell types [36], and chemicals [13], [18].

In the legal domain, the TREC conference had a dedicated track [7] for evaluating the application of Information Retrieval (IR) methods to e-discovery in the context of the U.S. civil litigation from 2006 until 2011 [26]. The Competition on Legal Information Extraction and Entailment (COLIEE) [19] ran over multiple editions allowed further exploration of tools and algorithms for information extraction in the legal domain.

This paper presents a manually annotated corpus comprising a subset of documents from the MAR-CELL Romanian corpus, with NEs in the legal domain. We considered the classical entity types (organizations, persons, locations) and time expressions as they appear in legal documents and added a new entity type in the form of legal references to documents (such as laws, government decisions).

The paper is structured as follows: in Section 2 we present related work; in Section 3 we introduce the annotation process; Section 4 describes different aspects of the corpus, such as the annotation levels, the representation of the linked data and statistics; Section 5 considers the usage of the RDF version; Section 6 presents use cases; Section 7 discusses quality and stability, and finally, we conclude in Section 8.

2. Related Work

In the context of the EU project "Multilingual Resources for CEF.AT in the legal domain" (MAR- $(CELL)^{1}$ a large comparable corpus of legal documents for seven languages was created [43]. Comparable corpora can be exploited for improving machine translation [24] and parallel sentences can be identified automatically, potentially containing NEs. The Romanian sub-corpus [41], as well as the other MARCELL corpora, was split at sentence and token levels, lemma-

¹https://marcell-project.eu/

tized, annotated at token level (part-of-speech, dependency parsing, NEs), and finally the corpus was enriched with IATE terms and EUROVOC descriptors. 3 All annotations in the Romanian MARCELL corpus 4 were realized using automatic processes.

6 Existing Romanian NE corpora include: RONEC [10], Romanian TimeBank [11] and SiMoNERo [1]. 7 The RONEC corpus contains 26,377 NEs, belonging 8 9 to 16 different classes. The Romanian TimeBank is an annotated parallel corpus for temporal information. Si-10 MoNERo is a gold standard corpus for the biomed-11 ical domain, manually annotated with four types of 12 domain-specific NEs. SiMoNERo has 14,133 NEs dis-13 tributed in 4,987 sentences. All these corpora contain 14 entities such as organizations, persons, locations. None 15 16 of these corpora contains legal texts or legal entities.

Dozier et al. [9] explore NER in legal documents 17 such as US case law, depositions, pleadings and other 18 trial documents. The types of entities include judges, 19 attorneys, companies, jurisdictions, and courts. 20

21 Cardellino et al. [3] explored using the LKIF ontology [16] further mapped to the YAGO ontology [39] 22 to train a NE recognizer, classifier and linker. The re-23 sulting system is applied to a corpus comprising judge-24 ments of the European Court of Human Rights. The 25 26 authors recognize that in the legal domain NEs are also names of laws, typified procedures and even con-27 cepts. Furthermore, when dealing with human anno-28 tators they observe that the classes and subclasses of 29 Document, Organization and Person were the most 30 consistent across annotators. 31

Glaser et al. [12] explored the suitability of NER 32 systems in the case of legal contracts. The entity 33 classes are person, organization, location, date, money 34 value, reference, and other. 35

36 Leitner et al. [22] introduced a German legal NE 37 corpus comprising seven coarse-grained and 19 finegrained classes. In this case, a "person" entity can be 38 classified into a regular person, a judge or a lawyer. 39 Similarly, a "legal norm" entity can be expanded into 40 41 law, ordinance or European legal norm.

In MARCELL, Romanian NEs were identified us-42 ing a general-purpose tool [28], available at that time 43 for the Romanian language, that was not adapted to the 44 legal domain, allowing only entities such as organiza-45 tion, persons, locations and time expressions. The tool 46 47 was not trained on any legal texts, but since no legal-48 domain tool was available it was used on this corpus. Thus, the need for a legal-domain NER corpus and sys-49 tem became apparent, which led us to the development 50 of the LegalNERo corpus. 51

3. Annotation process

Annotation was performed by five human annotators under the supervision of two senior researchers at the Institute for Artificial Intelligence "Mihai Drăgănescu" of the Romanian Academy (RACAI). Annotators followed specific guidelines², inspired by the Linguistic Data Consortium (LDC) guidelines³.

We considered five classes: person (PER), location (LOC), organization (ORG), time expressions (TIME) and legal document references (LEGAL). For person entities, we considered only person names. Titles and honorifics present in text near a person name were not included. Organizations must have some formally established association. Typical examples are businesses, government units and political parties. Locations are defined on a geographical basis. References are introduced similar to [21] and the coarse-grained class of [22], without additional sub-classes. Thus, they are references to legal documents such as laws, ordinances, government decisions, etc. Even though we only annotated the legal reference coarse-grained class, most of these entities can be mapped to fine-grained classes using automated processes, employing other linked data resources (Section 5).

Each annotator was given instructions on how to annotate the documents and then annotated a single document. We discussed issues or questions the annotators had. Subsequently, a collection of 100 documents was attributed to each annotator. Thirty documents (out of the 100) were shared with two other annotators, allowing us to compute inter-annotator agreement (IAA).

Corpus and account management for the annotators was realized through the RELATE platform [32]. Actual annotation was handled using BRAT [37], integrated into RELATE. This allowed the annotators to view one document, select the identified entity and then associate an entity type with the selected span.

After the annotation process, we computed IAA between each pair of annotators, using Cohen's Kappa. This was accomplished at token level and led to an average Kappa of 0.87. We further investigated the differences and were able to detect some recurring mistakes, such as the inclusion of indicative words in the entities (for example "orașul București"/"the city of

³https://www.ldc.upenn.edu/sites/www.ldc.upenn.edu/files/ english-edt-v4.2.6.pdf

Bucharest" instead of just "Bucuresti"/"Bucharest"). A 1 script was created to correct these mistakes. 2

Finally, we constructed an application to merge the 3 annotations into a single file. For each entity, the ap-4 5 plication shows all other entities overlapping the same 6 span and allows the user to select the entities that go in the merged file. To aid the user, the application highlights entities found by multiple annotators. 8

Once all common annotations were merged we 9 recomputed Cohen's Kappa measure between the 10 merged corpus and each annotator. This produced an 11 average Kappa of 0.89 and we consider this to be the fi-12 nal result. According to Landis and Koch [20], a Kappa 13 value greater than 0.81 is indicative of an "almost 14 perfect" agreement. The remaining disagreements ac-15 16 count for mistakes made by individual annotators, such as missing an entity or a sub-entity. This is particularly 17 reflected in potentially ambiguous situations such as 18 the legal reference "Regulamentul CE nr. 765/2008" 19 (en. "Council Regulation EC No 765/2008"). In this 20 case certain annotators identified "CE" as an organi-21 zation sub-entity, while others did not. In a few cases 22 the end-of-sentence punctuation coincides with the dot 23 indicating an abbreviation. Some annotators included 24 the punctuation in the organization entity abbrevia-25 tion, while others considered it to be sentence punctu-26 ation and did not include it (for example: "S.R.L." vs 27 "S.R.L" or "AFER." vs "AFER"). 28

4.1. Annotation levels

Raw text files were extracted from the Romanian 35 part of the MARCELL corpus. They contain national 36 legislation gathered by crawling from the public Ro-37 manian legislative portal⁴. As described in [43], the 38 texts were extracted from HTML and converted into 39 TXT files. For the LegalNERo corpus, we selected 370 40 documents of similar size, published between 2020-41 2021. We performed an initial check to ensure that the 42 files contain correct Romanian characters (with diacrit-43 ics) and do not contain tables or other structures that 44 may impact the annotations. 45

Annotation was performed using BRAT integrated into RELATE. Thus, the primary annotation output is represented by BRAT-specific files. Each line contains an entity ID, followed by entity type, text span (start and end) and the text. This annotation format allows for multiple annotations in overlapping spans.

We used UDPipe [38] on the text files for operations such as tokenization, lemmatization, part of speech tagging and dependency parsing. The resulting files were in CoNLL-U format⁵. We added a new column "RELATE:NE" (the 11th column) for NE annotations. We mapped the identified annotation text spans to tokens using a BIO notation format [35]. The associated entity annotation is prefixed with one of "B-" (for entity beginning) or "I-" (for a token inside the entity). Tokens that are not part of any entity are annotated with "O" ("outside").

The use of BIO scheme means that there is no support for overlapping entities. A token is associated with a single entity type. Therefore, we created two separate token-based annotations, stored in two folders: one for storing all entity types, without embedded entities, considering only the largest text spans, and another for storing only person, organization, and location entities and time expressions. Provision of the two folders means the corpus can be used either for legal domain annotations (considering the legal references) or for general annotations (the other entity types).

Initial annotations (BRAT and CoNLL-U Plus) were converted to RDF, specific to applications exploiting linked data. This increases the usability of the corpus and allows analysis using RDF queries and linking to external databases. Location entities can be resolved using geographical databases, such as GeoNames. The annotation is available in both CoNLL-U Plus files (column 12, "RELATE:GEONAMES") and in the RDF representation (Figures 1 and 2).

4.2. Linked data representation

Already having the text span annotations (in BRAT format) and the token-based annotations (in CoNLL-U Plus format) we were faced with the problem of designing a schema useful for linked data applications. We considered multiple types of ontology-based representations:

- CoNLL-RDF representation [5],[6]. It directly translates from tab-separated CoNLL format to RDF by employing the prefix "conll" with the column name. It associates a token representation with the NLP Interchange Format (NIF) [15].

Fig. 2. Token-based annotation in CoNLL-U Plus format.

- POWLA ontology [4], designed to support any kind of text-oriented annotation, allowing for "document layers" that contain the annotations.
- NERD ontology [34] provides classes such as "nerd:Location", "nerd:Person", "nerd:Organization" and "nerd:Time".
- European Legislation Identifier (ELI) ontology provides a framework for structuring metadata of legislative resources and publishing them as linked data. It provides the "eli:LegalResource" class which is defined as a work in a legislative corpus, applying to acts that have been legally enacted (whether or not they are still in force).
- GeoNames integrates geographical data such as the names of places in various languages, elevation, population and others. We linked location entities with GeoNames by using the feature identifiers. The annotation was performed automatically and then manually validated.

Table 1 presents the vocabularies used in the corpus. The key concepts and relationships expressed in the dataset are visualized in Figure 3, and a description is given in Table 2. Some of the vocabularies from Table 1 were used only as part of metadata specification. Therefore, they do not appear in the diagram. A complete example is included in Appendix A.

The corpus comprises multiple documents, represented as "powla:Document" elements. Each document is organized into three layers, corresponding to sentences, tokens and NE text spans. Each object's layer is indicated by the "powla:hasLayer" attribute and the layer is linked to a document using the "powla:hasDocument" attribute. Tokens are linked to sentences, using the "nif:sentence" and "powla:hasParent". The sentences document layer contains objects of type "nif:Sentence". To maintain the order of sentences, the "nif:nextSentence" and "nif:previousSentence" relations are used. Furthermore, the "nif:firstWord" and "nif:lastWord" attributes are employed to allow direct access to the first and last tokens of a sentence.

The named entities document layer contains elements from the NERD and European Legislation Identifier ontologies. The elements also inherit from "nif:Phrase", thus specifying the beginning ("nif:begin Index") and end positions ("nif:endIndex") for associated strings. Furthermore, the GeoNames feature identifier ("gn:Feature") is specified when available for corresponding "nerd:Location" entities.

V. Păiș et al. / LegalNERo: A linked dataset for named entity recognition in the Romanian legal domain

An example encoding in the LegalNERo corpus is given in Appendix A. where a token d1 s1 1 of type Word for the "nif" ontology and of type Node for the "powla" ontology is described. The example given in Appendix A corresponds to the sample ann and CoNLL-U Plus annotations given in Figures 1 and 2.

4.3. Statistics

Since the corpus is available in multiple representations, we follow each facet and present the corresponding statistics (see Table 3). Table 4 presents the distribution of the annotated tokens. The legal references class (LEGAL) contains 2,851 organizations (ORG) and 3,301 time (TIME) expressions. This format of the corpus also contains 1,411 GeoNames identifiers linked with the locations (LOC), where there is a complete overlap between the NE and GeoNames identifier. Table 5 gives the span-based statistics.

5. Using the RDF version of LegalNERo

The LegalNERo corpus [33] is available for download from Zeonodo⁶ as a single archive containing all 26 representations described in this paper. In the "rdf" folder there is a file containing all triples in RDF-Turtle. A SPARQL endpoint⁷ is available from the RELATE platform, offered via Apache Jena Fuseki, 30 with a graphical query interface⁸. Figure 4 presents a SPAROL query to list legal references. This type of queries is useful in creating gazetteer resources. 33

Additional examples are provided in Figures 5 and 34 6. In the first case, the SPARQL query allows listing of 35 location entities with associated GeoNames identifiers. 36 The result will contain only those entities that have 37 a GeoNames identifier. Figure 6 makes use of the to-38 ken layer and displays organization entities, tokenized, 39 with associated UPOS tags concatenated. In this ex-40 ample, only entities comprised of up to five tokens are 41 considered. This type of query is useful in finding pat-42 terns associated with the NEs present in the corpus. 43 Patterns can then be used with simpler pattern-based 44 NER systems, such as Stanford RegexNER, available 45 from the Stanford CoreNLP [23] package. 46

Fig. 4. SPARQL query to list legal references and result.

The advantage of having a linked data resource comes from the ability to interlink it with other resources. Recently, a number of other Romanian resources were converted to linked data format [2] and are available on the same SPARQL server as Legal-NERo. This enables complex federated queries to be performed across multiple resources. An example is the refinement of the legal reference class into multiple fine-grained classes. Considering the classes "law", "decision", "government decision", and "government ordinances", they correspond to the presence in the entity of different forms of the Romanian words "lege", "decizie", "hotărâre", and "ordonantă". Thus, we can exploit the RoLEX lexicon to obtain the word forms associated with the words and then use these to classify the existing entities (see Figure 7).

6. Corpus usage

In accordance with the LegalNERo corpus, we developed two NER models [27]: one for all the entities and expressions, and another dealing only with persons, locations, organizations and time expressions. These models are based on a recurrent neural network with a final CRF layer, trained using NeuroNER [8]. To improve performance, we used pre-trained word embeddings [31] representations trained on the Represen-

tative Corpus of Contemporary Romanian Language (CoRoLa) [42]. The models were integrated in RE-LATE [29, 32] and are available for online usage and download⁹, together with the embeddings¹⁰.

In the context of the "Curated Multilingual Language Resources for CEF.AT" (CURLICAT) project [44], we aim to develop an anonymization solution for Romanian. Part of this solution, we need the identification of NEs. Of course the purpose is not to anonymize legislation, but we consider that the NER models developed based on LegalNERo, have the ability to complement other models developed on more general cor-

the sense that we do not plan to change any of the classes or available attributes. Additions will be in the form of new data, following the same structure. Fur-thermore, any future extensions with regard to available NEs will follow the same general structure, with new classes being added, without removing existing information. Finally, the versioning system provided by Zenodo allows retrieval of the corpus at any point in time and ensures its continuous availability.

Metrics for assessing linked data quality have been proposed [25, 46], considering both the data content and the metadata. The embedded metadata provides an indication of the dataset provenance, improving also the trustworthiness of the dataset. We offer the corpus under a Creative Commons licence (CC BY-ND 4.0).

This information is also part of the metadata (machinereadable) and indicated in human-readable format on the corpus download page.

Before release, the dataset was checked for syntactic validity and no errors have been found. Furthermore, there are no consistency issues with regard to the data structure (no misplaced classes or properties, no inconsistent values). With regard to the actual annotations, the only inconsistencies may arise from the IAA (Section 3). The SPARQL endpoint is offered from a research server, shared with other projects, and thus performance metrics (such as low latency, high throughput or scalability) were not considered.

Fig. 7. Classify legal reference entities into fine-grained classes.

8. Conclusion and future work

This paper introduced the LegalNERo corpus, a manually annotated corpus for NER considering legal references in the Romanian language, providing spanbased annotations, token-based annotations and RDF-Turtle format. The corpus represents a subset of the MARCELL [43] legislative corpus; for certain applications these corpora could be used together. LegalNERo also provides annotations for sub-entities present inside the legal references. This can be exploited to allow usage of the corpus for training more classic NER systems considering only persons, locations, organizations, and time expressions. We further offer a SPARQL endpoint. Finally, the corpus was integrated into the Linked Open Data Cloud¹².

Our aim is to further use this corpus to construct an improved NER system for the Romanian legal domain. Currently available models achieved an average F1 score of 84% (considering all entities) and 84.70%

¹²https://lod-cloud.net/dataset/racai-legalnero

(without the legal reference entity type). This already presents an improved performance compared to the one [28] previously used to automatically annotate the Romanian Legal Corpus [41]. We re-evaluated the old NER system [28] on the LegalNERo corpus and it achieved only a 49.38% average F1 score (with individual F1 scores 84.06% for time expressions, 56.7% for organizations, 26.85% for locations, and 19.3% for persons). This difference comes from the lack of legal-domain text used in training the old system. Even though the size of the corpus is small, it has proven useful in improving the performance of the NER system and can be considered an important first resource for NER for the Romanian language in the legal domain. Considering additional techniques, such as word embedding combinations [30] could prove beneficial in improving the overall performance.

Acknowledgements

Part of this work was conducted in the context of the "Curated Multilingual Language Resources for CEF.AT" (CURLICAT) project, CEF-TC-2019-1 – Automated Translation grant agreement number IN-EA/CEF/ICT/A2019/1926831.

```

The corpus object is encoded as "c1" (classes "powla:Corpus", "dcat:Dataset"). Documents ("powla:-Document") contain "powla:DocumentLayer" for sentences ("d1_l_sent"), tokens ("d1_l_tok"), and entities ("d1_l_ner"), and are linked to the corpus ("powla:hasSuperDocument") (see "d1"). Sentences ("nif:Sentence") are linked to the appropriate document layer. Individual tokens ("nif:Word") contain conllu annotations and are linked to the sentence ("nif:sentence") and to the tokens layer, using the relation "powla:hasLayer" (see "d1_s1_1"). Span-based entities (see "d1_e1") belong to NERD classes or "eli:LegalResource". These are linked to the NER layer and contain the start ("nif:beginIndex") and end ("nif:endIndex") indexes. Object names are encoded using an initial letter ("c" - corpus, "d" - document, "s" - sentence, "e" entity) followed by a number ("d1_s1" means the first sentence of the first document).
