Abstract. Applied research and prototypes constitute an important part of the initiative around Stream Reasoning (SR) research. From Social Media analytics to the monitoring of IoT streams, the SR community worked hard on designing working prototypes, query languages, and benchmarks. Applied work that uses stream reasoners in practice often requires a data modeling effort. For this purpose, RDF Stream Processing (RSP) engines often rely on OWL 2 ontologies. Although the literature on Knowledge Representation (KR) of Time-varying data is extensive, a survey investigating KR for Streaming Linked Data is still missing.

In this paper, we describe an overview of the most prominent ontologies used within RSP applications and compare their data modeling and KR capabilities for Streaming Linked Data. We discuss these ontologies using three complementary KR views, i.e. viewing the streams as Web resources, a view on the structure of the stream, and a view on the modeling of the events in the streams themselves. For each view, we propose an analysis framework to facilitate fair comparison and in-depth analysis of the survey ontologies.

Keywords: Stream Reasoning, RDF Stream Processing, Web Stream Processing, Knowledge Representation

1. Introduction

In recent years, the Semantic Web community has witnessed a growing interest in streaming data for application domains that combine the presence of Data Variety (i.e., highly heterogeneous data sources) with the need to process data as soon as possible and before they are no longer useful (Data Velocity). Examples of such application domains include Smart Cities, Industry 4.0, and Social Media Analytics. Stream Reasoning (SR) [62] is a research initiative that combines Semantic Web with Stream Processing technologies to the extent of addressing the aforementioned challenges at the same time. SR counts several research outcomes that span across Continuous Querying, Incremental Reasoning, and Complex Event Recognition [29]. RDF Stream Processing (RSP) is a subarea of SR that focuses on the processing of RDF Streams [58]. In particular, the research activities around RSP, include a growing number of applied research works due to the availability of working prototypes, benchmarks, and libraries [45] that, in turn, spawn research on Streaming Linked Data [59, 64].

While data streams become more available on the Web, the community started discussing best practices to publish data streams in an interoperable manner. To
this extent, the FAIR data initiative is promising. Indeed, Tommasini et al. reinterpreted some of the steps of the linked data lifecycle to answer the question "how can we make (streaming) data Findable, Accessible, Interoperable, and Reusable (FAIR) [59]?

Tommasini et al. consider several resources published under the SR umbrella. A number of works emerged that show how to access and process data streams on the Web [45]. Even though a number of domain-specific ontologies have been used in Streaming Linked Data applications, little has been done regarding the data modeling and knowledge representation efforts that Streaming Linked Data applications entail.

In this paper, we dig deeper into this claim by surveying the related literature and isolating such efforts. In particular, we investigated research papers that apply RSP, i.e., a subset of SR, as a solution. Like in similar works, we systematically select the papers, defining inclusion criteria and filtering methods. We extracted the used ontologies from these selected papers to model the data streams. We study such ontologies from three perspectives: (i) A Thirty-Thousand Foot View, which observes streams as Web resources analogous to dataset yet characterized by the velocity of changes; such view surveys existing practices for data modelling and KR for data streams. This view follows a top-down approach and starts from the FAIR principles [67] and verifies the compliance of several FAIR principles under survey. (ii) A Ten-Thousand Foot View, which gets closer to the streams and investigates its content; the result is a meta-conceptualization that empirically describes the structure of Streaming Linked Data vocabularies and ontologies. The definition of such a framework is guided by a review of existing stream processing conceptualizations [1, 4, 19]. (iii) A Thousand Foot View that narrows down even more until observing the internals of the items that populate a data stream, i.e., events. Thus, such a view leverages the Common Event Model [66] to study and explain how structurally Streaming Linked Data are presented. Our analysis shows how such a view complies with the inner parts of the stream representation.

Figure 1 summarizes our three-folded perspective, designed to highlight different aspects concerning knowledge representation for Streaming Linked Data by progressively zooming in. Indeed, higher levels offer a broader analysis than the ones below, encouraging a holistic view of the central concepts, i.e., Data Streams and their interrelations (30k), the classes and properties characterizing the content of data streams (10k), and the structure of the event as the unit of information that populate the streams (1k).

Outline: Section 2 introduces the necessary background to understand the content of the paper. In Section 3 we introduce the ontologies that are being investigated. Sections 4, 5, and 6 present the three views from higher to lower. Section 7 proposes a number of best practices and Section 8 details the related work and Section 9 concludes the paper.

2. Preliminaries

In this section, we present the fundamental notions needed to understand the content of the paper. In particular, we present the survey methodology and the Streaming Linked Data lifecycle.

2.1. Survey Methodology

Our survey follows the guidelines of the systematic mapping research method [20], which has been already used successfully for surveys in the Semantic Web [51]. In particular, our investigation aims at answering the following research question (RQ):

RQ1 What characterizes the knowledge representation efforts for managing heterogeneous data that are streaming or highly dynamic?

The integration of heterogeneous data is a significant part of Semantic Web Research. In addition, RQ1 includes two main components, i.e., Streaming/Highly Dynamic Data and knowledge representation. The former relates to application domains like the Internet of Things or Social Media Analytics (but also financial analysis, Smart Cities, and cluster management). The latter is central in applications that deal with complex information needs. Together, they point to contributions from the Stream Reasoning community and, in particular, to Streaming Linked Data. Indeed, under the SR initiative several engines, query languages, and benchmarks were proposed to address Streaming Linked Data use cases.

To collect relevant studies, we initially conducted a keyword-based search on Google Scholar, the IEEE Xplore, and the ScienceDirect and investigated their citations to retrieve further interesting studies. We used the following keywords to retrieve 620 papers:

- Stream Reasoning
- RDF Stream Processing
The next steps of our collection apply a number of filters to reduce the number of papers and narrow the analysis. To this extent, we identified different inclusion criteria (IC) indicated below. Notably, IC1-4 are based on the papers’ metadata, while IC5 and IC6 are content-based.

IC1 papers should be written in English
IC2 papers should be peer-reviewed
IC3 papers should be published in the last 10 years,
IC4 papers should have at least 10 citations.
IC5 papers should apply a SR/RSP solution to process data streams,
IC6 papers should present/reuse a domain-specific ontology to model the data in the processed streams,

Like in [51], we apply Metadata-based filtering to the papers, screening their title, abstract, and publication venue and, then, we apply the Content-based filtering step drilling down to the papers introduction, conclusion and if needed, the full text. Finally, we proceeded with an enrichment step (aka snowballing) which aims at expanding the relevant papers based on investigating their citations and related work. Especially for papers proposing Streaming Linked Data engines, it was very beneficial to investigate their citations as it revealed many use case papers.

Our analysis identified 32 papers from which we extracted 10 ontologies. The extracted ontologies are commonly used in one or more of the identified papers. The last step of our analysis was dividing the ontologies into two groups. The first group addresses Streaming Linked Data from a publication/discovery standpoint. Given the abstract view, we name such group Thirty-Thousand Foot View. The second group looks at Streaming Linked Data from a processing standpoint, which is a lower level of abstraction. Therefore, we name this group the Ten-Thousand-Feet View. We also notice that within the latter group, there is even a lower abstraction point of view which we name the Thousand Foot View and concerns the representation of data points within the streams. Figure 2 visualizes the selection process, while Table 1 lists the selected ontologies, their prefixes, each view they cover, and the papers they originated from.

2.2. Streaming Linked Data Lifecycle

The Streaming Linked Data Lifecycle [16] proposes a number of guidelines on how to manage data streams on the Web. Figure 3 depicts the full life-cycle and highlights the Model and Describe steps which both require a knowledge representation effort. The Model step takes care of modeling the content of the stream using a certain ontology-based knowledge representation, while the Describe step focuses on describing the stream itself as a Web resource. The latter aligns with the Thirty-Thousand Foot View, while the former aligns with the Ten-thousand and Thousand Foot View. Each of these steps requires the use of stream-specific ontologies and (rich) metadata. While the other steps are out of scope for this paper, it is worth mentioning that Step (0) is about naming Web Streams using appropriate URIs; Step (2) is about structuring of stream data events; Step (3) focuses on converting streaming data into a machine-readable format; Step (5) is about serving data using protocols that enable continuous data access (e.g., WebSockets), and Step (6) relates to Web Stream Processing.
3. Selected Works

This section details the selected SR ontologies that will be investigated using the proposed Thirty-Thousand, Ten-Thousand, or Thousand Foot View.

3.1. Foundational Ontologies

We first describe four general ontologies that are frequently imported into the SR ontologies we will discuss later. Moreover, we highlight parts of their conceptualizations that are relevant to understand the content of the paper.

**OWL Time**\(^1\) is an ontology that captures temporal concepts. It is extensively used to describe the temporal properties of Web resources. OWL Time models both temporal intervals and instants. Its conceptualization includes, but is not limited to, dates, temporal entities, and Allen’s Algebra Relations.

**PROV-O**\(^2\) captures the PROV data model using OWL2. The ontology aims at enabling provenance information exchange across systems.

**DCAT**\(^3\) is an RDF vocabulary designed to foster interoperability among data web-published catalogs. It focuses on describing how data catalogs and datasets are accessible and distributed.

**Event Ontology**\(^4\) is an OWL ontology originally designed in the context of the Music Ontology by the Centre for Digital Music. The ontology was intended to describe performances, compositions, recordings, or sound generation. Nevertheless, its generality fostered its adoption making EO the most used event ontology in the Linked Data community [54].

### 3.2. SLD-Specific Ontologies

When surveying the literature, we found that the following ontologies are being used for the description and modeling of streaming data as Web resources:

<table>

Table 1: Ontologies for Streaming Linked Data: Summary. (✓: supported, ✓: partly supported)

---

\(^1\)https://www.w3.org/TR/owl-time/
\(^2\)https://www.w3.org/TR/prov-o/
\(^3\)https://www.w3.org/TR/vocab-dcat-2/
\(^4\)http://motools.sourceforge.net/event/event.html
\(^5\)http://citypulse.insight-centre.org/ontology/ces/
formation by distinguishing primitive and complex event services. Notably, CES was designed to be used in combination with SAO and, thus, we consider them together in our analysis [33].

**Linked Data Event Stream (LDES)**\(^{6}\) defines a collection of immutable objects that evolves over time, describing both historical and real-time updates. **LDES** uses the ** TREE** specification\(^{7}\) for the modeling of the collections and data fragmentation purposes when the size of the collections becomes too big for a single HTTP response. **TREE** defines a collection of objects that adhere to a certain SHACL shape, and how these collections can be fragmented and interlinked using multi-dimensional HTTP pagination [64].

**IoT Stream** a vocabulary for the annotation of (IoT) streams. It extends the **SSN** ontology (see below) with the notion of Streams, Events and Analytics that can be extracted from the streams [31].

Furthermore, we additionally identified the following prominent ontologies used in RSP applied research and will investigate their structure and internals when used as a knowledge representation in stream reasoning applications:

The **Semantic Sensor Network (SSN)**\(^{8}\) is the W3C recommendation to describe sensors, platforms, devices, and observations [56].

The **Sensor Observation Sampling Actuator**\(^{9}\) (SOSA) ontology is the result of the community attempt to rewrite SSN to the extent of making the ontology more usable. The ontology integrates many rewriting proposals and ultimately reduces the ontological commitment of SSN by selecting a core module relevant for most IoT applications. It is a modular ontology design, where SSN can be seen as an extension of SOSA.

The **Smart Applications REFeRence ontology**\(^{10}\) (SAREF) aims at enabling interoperability between different IoT providers. It is similar to SOSA/SSN but provides specific classes for sensors and observations (called **Devices** and **Measurements**), in comparison with SSN, which is very generic. SAREF thus has various extensions tailored for specific domains.

The **Linked Open Descriptions of Events (LODE)** is an RDFS vocabulary that aims at unifying existing event ontologies, such as the Event Ontology. LODE represents only facts using the 4W framework, i.e., What, When, Where and Who [54].

**Frappe** is a vocabulary for spatio-temporal streaming data analytics. Frappe borrows its conceptualization from the domain of photography. It represents the world as a sequence of frames. Events occur within a spatio-temporal context. To represent the spatial context Frappe uses three classes, i.e., Grid, Cell, and Place, and models time using the **OWL Time ontology** [11].

The **Semantically-Interlinked Online Communities (SIOC)** describes the information that online communities (e.g., wikis, weblogs, social networks, etc.) have about their structure and online community content [21].

The **Activity Streams 2.0 (ActS)**\(^{11}\) vocabulary includes classes and properties to describe past, present and future activities. The vocabulary consists of (i) a core that generalizes the structure of an activity, and (ii) an extended module that includes properties that cover specific types of activities common to many social Web application systems.

All surveyed ontologies, their prefixes and which views they cover are summarized in Table 1. Figure 4 visualizes the dependencies between the various selected SLD ontologies and the imported concepts or complete ontologies that they share. Certain SLD ontologies do not import a whole ontology, but rather im-

port a limited subset of concepts of a certain ontology, this is visualized with the full dependency arrow in Figure 4, while complete imports of ontologies are visualized with dashed arrows. Note that the figure only depicts overlapping imports, i.e. imported ontologies that at least two ontologies share. Ontologies imported by a single SLD ontology are not depicted in order to keep a visual overview.

4. Thirty-Thousand Foot View: Web Streams

The thirty-Thousand-Foot View for Streaming Linked Data observes data streams as Web resources, i.e., the fundamental building blocks of the World Wide Web, and focuses on their metadata, governance, and provenance. Therefore, we reformulate our research question as follows:

RQ$^{30K}$ What characterizes the knowledge representation efforts for managing streaming (or highly dynamic) heterogeneous data, when the modeling focuses on streams and their content as referential Web resources

Only four of the ten selected ontologies have the notion of data streams as Web resources, the others are not included in this discussion. These four ontologies include VoCALS, SAO/CES, LDES, and IoTStream.

4.1. Analysis Framework

Our analysis builds upon the preliminary adaptation of the FAIR principles proposed in [59]. The original FAIR Principles [67] are reported below:

**Findable.** (F1) Data should be assigned unique and persistent identifiers, e.g., DOI or URIs. (F2) Data should be assigned metadata that includes descriptive information, data quality, and context. (F3) Metadata should explicitly name the persistent identifier since they often come in a separate file. (F4) Identifiers and metadata should be indexed or searchable.

**Accessible.** (A1) Data and metadata should be accessible via (a) free, (b) open-sourced, and (c) standard communication protocols, e.g., HTTP or FTP. Nonetheless, authorization and authentication are possible. (A2) Metadata should be accessible even when data is no longer available.

**Interoperable.** (I1) Data and metadata must be written using formal languages and shared vocabularies that are accessible to a broad audience. (I2) Such vocabularies should also fulfill FAIR principles. (I3) Data and metadata should use qualified references to other (meta-)data.

**Reusable.** (R1) Data should adopt an explicit license for access and usage. (R2) Data provenance should be documented and accessible. (R3) Data and metadata should comply with community standards.

Notably, the Thirty-Thousand Foot View does not aim at assessing whether existing ontologies follow the
FAIR principles themselves (as similar effort has been
done in previous research [49]). Instead, the analysis
investigates if existing ontologies allow to share FAIR
streaming data on the Web. The analysis focuses on the
ontological level and its (potential) applications. Defi-
nition 1 introduces the notion of Web Stream, which is
a prerequisite for identifying streams on the Web.

Definition 1. A Web Stream is an unbounded ordered
collection of pairs \((o, i)\), where \(o\) is a Web resource,
and \(i\) is metadata that can be used to establish an or-
dering relation, e.g., a timestamp.

Definition 1 subsumes two levels of discussion con-
cerning the data and metadata, i.e., a Stream Level and
an Event Level. In the former case, the data are the
streams and how they connect to each other, domain-
specific entities (e.g., their authors), and to the ele-
ments they contain; the metadata, in this case, it is
similar to those relevant for datasets, e.g., the date on
which a stream was first issued, made available, or
modified or information about the various data distri-
butions or formats that the stream is available in, but
also, the number of distinct subjects in the dataset. At
the Event Level, instead, the focus is on the Web re-
sources within the stream and how they connect to each
other, and to domain-specific entities (e.g., a Point
of Interest or a person). In this case, metadata relates to
the event order, like their timestamp, but also duration,
or location.

4.2. Discussion

We now analyze the selected ontologies, w.r.t. the
FAIR data principles. While Table 3 summarise the an-
wers to the individual principles, we organize the dis-
cussion along the following dimensions by answering
the related questions:

D.1 Identity (F1, F3, A2): Is it possible to use IRIs
or DOIs to identify the Web Stream and/or the referred
resources in ontology X?

VoCALS, LDES, and IoTStream, introduce very similar
concepts that lead to instantiating referencable
Web Streams. More specifically, VoCALS includes
the notion of voc:Stream specifically to repre-
sent an unbounded dataset on the Web; LDES in-
troduces the notion of ldes:EventStream as an
append-only collection of immutable elements, and
assigns to it a retention policy; Elsaleh et al. in-
clude in their IoT Stream ontology the notion of
iot:IoTStream. SAO goes one step further, allow-
ing its users to identify the resources within the stream
as sao:StreamData or sao:StreamEvent; the
two classes distinguish the raw elements from those
produced by some analysis. The class sioc:Thread
and the more generic sioc:Container refer to a
collection of elements. However, they do not explicitly
mention an ordering relation between them. Similarly,
ActS includes the concept of OrderedCollection
that aligns with the Web Stream Conceptualisation,
while individual activities represent elements in the
collection. Finally, LODE allows only the instantia-
tion of individual events without conceptualizing the
Web Stream. Although the presence of a class that
aligns with the conceptualization in Definition 1 does
not prevent instantiating the stream anonymously (with
blank nodes), it allows the FAIR usage with transpar-
ent IRIs/DOIs (F1).

D.2 (Meta)Data Semantics (F2, I1, R1): Can the ont-
ology X capture the \((\text{meta})\)data semantics at stream
and event level? What formalism was used for the mod-
eling efforts?

Among the selected ontologies, only five have a
conceptualization that can be coherently aligned with
Web Streams and, thus, allow representing stream-
level data. VoCALS and LDES allow specializing RDF
Streams, but they do not specify anything regarding the
event-level semantics. On the other hand, SAO/CES,
IoTStream, SAREF, and SSN/SOSA focus only on rep-
resenting data only at the event level, following a com-
monly accepted ontology design pattern for modeling
sensor measurement in RDF based on observations.
Also LODE, and Frappe neglect the stream level (as
seen before) and focus only on the event level dimen-
sion for data and metadata. Finally, SIOC, ActS are the
only two ontologies that can possibly define data at
both stream and event level, nonetheless, with some
limitations wrt. the conceptualisation of Definition 1.

Regarding metadata, VoCALS supports to descrip-
tive information about the resources, e.g., name and
owner, and contextual information, e.g., the vocabu-
ulary used to annotate the stream content, as well as
stress on the specification of a license (R1). Instead,
LDES explicitly supports only contextual metadata as
it relies on the TREE specification, which also includes
a license (R1). Notably, also SAO/CEO supports li-
censing via the imported ontology QOI. Although not
explicitly declared, the same approach would be pos-
sible in SIOC and ActS, as both have a concept that
can be aligned to Web Streams. Finally, neither SIOC
and ActS, nor SAO/CES, IoTStream, SAREF, and SS-
N/SOSA do explicitly define event level metadata.

Table 3

Summary of the thirty-thousand-foot view, i.e., compliance of the Selected ontologies (top) with FAIR Principles (left) and our analysis dimensions (left) (Terminological Level Only) Legend: o=possible; ✓=supported; ≈=partially supported; [S]tream; [E]vent; [G]eneral; [D]escriptive; [C]ontext; [P]rovenance; [I]ndexing; [U]nordered; [N]ot [A]pplicable.

Finally, all the selected ontologies use OWL (Frappe, VoCals, SAREF, SAO/CES, IoTStream, SSN/SOSA) or RDFS (Activity Streams, SIOC) as ontological languages to implement their formalization.

D.3 Data Models (F3, R3) and Adequate Protocols (A1, A2): Can adequate access protocols for streaming (meta)data and be defined using ontology X? Are the (meta)data appropriately licensed, and is the licensing specific to the stream? Can (meta) data stream be represented using the RDF data model in ontology X?

All the selected ontologies support and encourage using RDF (Streams) to represent data and metadata (F3). However, not all focus on the stream and event levels. VoCals and LDES even explicitly include an RDF Stream specialization of the generic data stream. Although choosing an adequate protocol for sharing (meta)data on the Web usually means HTTP, it does not directly apply to streaming data. Regarding sharing, VoCALS and LDES adopt the convention, introduced initially by Barbieri et al. [13], who suggested sharing the stream metadata in a separate document accessible via HTTP while adopting a more suitable protocol for the stream content (F3, A2). Notably, the same approach would be possible with the SIOC and ActS given that we could find an alignment with the concept of a Web Stream. Finally, except LDES, which inherits the HTTP access assumption from TREE, the other ontologies include a specific abstraction that aims at generalizing access to the streaming data. Still, they do not recommend explicitly any protocols except IoTStream (e.g., RESTful, NGSI-9, MQTT, CoAP etc.), i.e., voc:StreamEndpoint, sioc:Space (is a place where data resides, e.g., on a website, desktop, fileshare, etc.) iots:Service, saref:Service, ces:EventService.

D.4 Data Quality (F2, F4, R2): What dimensions of data quality does ontology X consider?

Among the selected ontologies, only SSN, SAO/CES, and IoTStream explicitly focus on data quality by including specific classes and properties. Their modeling is thorough, and it includes all the traditional data quality dimensions like Accuracy, Volatility, and Completeness. For the sake of the analysis, we discuss them as part of a General definition [48], distinguish them from other aspects related to Descriptive and context-
ual metadata, or traceability, which is another essential dimension of data quality that is explicitly named by FAIR principles (R2) as Provenance. 

SSN System Capabilities Module\textsuperscript{12} includes several dimensions, e.g., ssn-system:ResponseTime, ssn-system:Frequency, or the conceptualization of ssn-system:Drift. SAO/CES, and IoTStream import many dimensions from the Data Quality Ontology QOI \textsuperscript{13}, for example qoi:Accuracy, or qoi:Completeness, or qoi:Jitter.

Moreover, VoCALS, LDES, IoTStream, as well as SIOC, SSN, and ActS (although implicitly), includes classes and properties for describing the streams and linking to contextual resources, e.g., services that can contribute to the quantification of the quality level.

Regarding provenance (R2), all the ontologies, except for LDES, which is not focused on processing, include dedicated classes and properties for tracking the provenance of streaming analysis, i.e., vocals:Task and vocals:Operator for representing queries, ces:StreamAnalysis and ces:EventPattern for aggregations and complex event recognition, for spatio-temporal analyses frappe:Synthetize and frappe:Capture, and saref:Function and iots:Analytics or ssn:Procedure for continuous processing over the observation streams.

Finally, LODE does not support any data quality dimension. At the same time, all the ontologies that allow the usage of explicit identifiers support indexing and searching for URIs.

D.5 FAIR Referencing (12, 13): Does ontology X provide explicit mechanisms for referencing external (FAIR) resources, such as connecting the stream and its items?

Linking across resources is essential to the Semantic Web and, more generally, interoperability. Also, the FAIR principle encourages this, translating at the ontological level with the explicit possibility of linking to external resources (outside the (meta)data semantics). Not all the ontologies support it explicitly, but only VoCALS allows to connect a given Web Stream with vocabularies, mapping files, and/or ontologies; LDES via the tree:member inherited from TREE, which allows connecting any referentiable resources to the stream or its elements; ActS, with the class Link that is meant to be an indirect reference to another resource, and finally LODE, which includes two proper-

5. Ten-Thousand Foot View: Streams’ Structure

The Ten-thousand Foot View focuses on the ontological level and analyses the nature and nurture of the conceptualization of the selected ontologies used for representing streaming data within a given domain.
Fig. 5. Streaming Linked Data Abstractions

**RQ10** What characterizes the knowledge representation efforts for managing streaming (or highly dynamic) heterogeneous data, when the modeling efforts are tailored for a given application domain and must consider domain-specific entities?

According to our Thirty-Thousand Foot View analysis (see Table 3), only eight of the ten selected ontologies describe concepts to represent the streaming data at the event level. These eight ontologies include SSN/SOSA, SAREF, IoTStream, SIOC, LODE, ActS, Frappe, and SAO/CES. The other ontologies are not included in this discussion.

### 5.1. Analysis Framework

In the related literature [4, 28, 45], dynamic data are typically divided into two kinds of abstractions, i.e., unbounded time-ordered data a.k.a. streams and Time-varying ones. Arasu et al. [4] introduced such data dichotomy to the extent of formalizing relational Continuous Queries. Dell’Aglio et al. [27] extended it later on for RSP. In this work, we focus on Streaming Linked Data and, thus, RDF Streams (see Definition 2).

**Definition 2.** An RDF Stream is a Web Stream such that o is an RDF object, i.e., an RDF graph, a quad, or a triple, and \( \tau \in T \) is a timestamp. An element \((o, \tau)\) is said to be instantaneous, to highlight its validity at a precise point in time \( \tau \).

Streaming Linked Data focuses on query answering over RDF Streams, i.e., Continuous Computations (see Definition 3) that assume the form of Continuous Queries (CQ), which are a special class of queries that listen to updates and allow interested users to receive new results as soon as data becomes available.

**Definition 3.** Continuous Computations proceed under continuous semantics, i.e., they output an infinite stream while consuming one or more infinite streams as inputs.

On the other hand, Time-varying abstractions represent the result of Continuous Computations and, as the term suggests, capture the changes that occur to data as a function of time. Definition 4 formalizes the notion and specializes the definition for RDF data.

**Definition 4.** Time-varying Abstractions (TVA) are functions that map the temporal domain to finite entity sets that relate to a given abstraction \( T \rightarrow A \).

In particular, a Time-varying RDF Graph is a function \( T \rightarrow G \), where \( T \) is the time domain and \( G \) is the set of possible RDF graphs.

Many extensions of SPARQL exist [29] to perform Continuous Queries over RDF Streams, and the RSP-QL [27] reference model aims at unifying the formal semantics of existing SPARQL extensions. Its abstraction can be found in Figure 5. A common aspect of these languages is the notion of windowing, which allows to perform stateful computation over a stream. Window Operators, a.k.a. Stream-to-Relation (S2R) operators, chunk the stream into finite portions where computations can terminate. Once windows are applied, operators that involve Time-varying abstractions can be traced back to their original version that is applicable to static data (R2R). Finally, an operator’s class that transform back Time-varying data into streams is called Relation-to-Stream (R2S). According to RSP-QL, a Time-varying RDF Graph is the result of the application of a window operator over a stream.

Last but not least, static data co-exist with both streaming and Time-varying ones. Indeed, stream enrichment with contextual static knowledge is a popular task in SR/RSP [45].

### 5.2. Discussion

In this section, we elicit the data dichotomy explained above to study the meta-conceptualization of the selected ontologies that model concepts that are in line with the meta-conceptualization described above. For this reason, LDES is not taken into account in this discussion.

An ontology used for SR typically consists of five levels, i.e., \( L1 \) the instantaneous level identifies the part of the ontology that is directly associated with a temporal annotation. Entities of this kind occur in the stream. \( L2 \) the static level of the ontology identifies those concepts that may have a temporal annotation, but that are assumed to not change while the Continuous Computation occurs. This level is relevant for the stream enrichment task [45]. For the sake of completeness, we also include a time-agnostic level \( L3 \), which identifies those ground terms that are indepen-
dent of time. L4 the Time-varying level includes entities whose state evolves over time. Entities of this kind are typically the result of a Continuous Computation, e.g., an aggregation. Last but not least, we include the continuous level L5 to identify those terms that combine other terms and return Time-varying entities as a result of processing. Entities of this kind typically include continuous transformations or queries. Notably, due to the lack of space, we leave a deeper investigation of L5 as future work.

While the detailed analysis of the selected ontologies is presented below, it is also summarized in Table 4. Figure 6 depicts that decision diagram that allows to assign ontology concepts to the proposed meta-structure of the Ten-Thousand Foot View.

**Instantaneous (L1).** There is a clear agreement between the IoT ontologies (SSN, SOSA, and IoT-Stream) which identify the `sosa:Observation` on their instantaneous level. SAREF’s conceptualization is slightly different as `srf:Measurement` already includes the unit of measure. On the other hand, SAO/CES adopt a generic data item using the classes `sao:StreamData` and `sao:Point`. SIOC and ActS present a small hierarchy of concepts, i.e., `sioc:Post`, `sioc:Item`, and `as:Activity` that capture the interaction with social networks (or general Web interactions). Frappe and LODE adopt the concept of `Event`, which both align with the Event Ontology.

**Static (L2).** Also for the static level, the IoT ontologies share a similar conceptualization, i.e., `Device`, `Sensors`, and `Platforms` are entities that are assumed to be static when the analysis occurs. Frappe’s static part includes concepts for representing spatial information. ActS’ static part is limited to the `as:Actor` class and its sub-classes. SIOC’s static

part relates to Users and Spaces that represent the population and logical location of online communities. LODE does not include concepts at L2. Notably, VoCaLS includes Stream and RDFStream as static concepts. In fact, they are meant to represent streams as resources (to be continuously consumed).

**Time Agnostic (L3).** Neither Frappe nor SAO/CEO, which were originally designed for SR/RSP applications, directly include L3 concepts. On the other hand, the IoT ontologies include concepts that do not directly have a temporal dimension. Such entities are related to the properties observed from the sensors and the unit of measurement. While LODE does not include concepts at L3, SIOC and ActS respectively have only one, i.e., sioc:Role that represent the role of a sioc:User on a sioc:Space and as:Link that represent a generic connection between two resources.

**Time Varying (L4) and Continuous (L5).** Except for LODE all the selected ontologies present a Time-varying part. On the other hand, L5 remains uncovered by LODE, SIOC, and ActS. Interestingly, L4 is where the selected ontologies differ the most. SSN/SOSA distinguish between the ssn:Result of a ssn:Procedure, and the action taken after processing, i.e. a ssn:Actuation. SAREF represents Continuous Computations as Functions that aggregates Measurements to modify a srf:Device's srf:State. IoTStream's continuous part is called an iots:Analytics and produces iots:Events as Time-varying entities. SAO/CES include the class sao:StreamAnalysis too. However, the result can be either a sao:StreamEvent or a sao:Segment, which is just a portion of the stream. Frappe includes a Time-varying corresponding entity for both the static entities frp:Grid and frp:Cell, i.e., frp:Frame and frp:Pixel. As briefly mentioned, it also represents continuous entities, i.e., frp:Capture and frp:Synthesize. Last but not least, VoCaLS includes two entities inspired by RSP-QL [27], i.e., TimeVaryingGraph that represents the Time-varying equivalent of an RDF Graph, and SDS, which is a collection of TimeVaryingGraphs. Moreover, VoCaLS explicitly mentions continuous transformations, i.e., Task and Operator. The former is meant to generalize Continuous Queries, while the latter helps tracking provenance by representing the task internals.

Table 5

Ontology expressivity in terms of OWL2 Profile and Description Logic

We can see that most ontologies distribute the ontology complexity across different temporal levels, facilitating the alignment with SR applications.

### 5.3. Reasoning Capabilities

The survey ontologies describe various complex concept definitions which require some form of reasoning in order to correctly interpret these definitions. We investigate the expressivity of each ontology and how the presented meta-structure relates to various reasoning perspectives that provide opportunities for optimizations. Table 5 shows the expressivity of each ontology in terms of required OWL2 Profile and Description Logic (DL) expressivity\(^\text{14}\) to fully interpret the ontology. An important observation is that most ontologies are very expressive, i.e. requiring the OWL2 DL Profile to be fully interpreted. However, there is a mismatch between the complexity of the reasoning algorithms required to interpret these ontologies and the frequency that data is updated in SR applications [18], making these ontologies at first glance ill-suited for SR applications. For the ontologies that have import statements, i.e. Frappe and VoCaLS, we make a distinction between the expressivity of the core ontology with and without its imported ontologies. We can see that both ontologies owe their high expressivity to their imported ontologies as their own concept definitions are much lower in expressivity.

\(^{14}\)We refer the reader to Baader et al. [5] for a complete introduction to DLs, as it is out-of-scope for this paper.
We now zoom deeper into various complex definitions and their structural relation to SR tasks. As the goal in SR applications is to reason upon the events in the stream and combine them with other contextual data, we investigate complex concept definitions that span across the Instantaneous level (L1) and any other level. We define complex concept definition in DL notation, i.e. $B \subseteq H$, which informally could be interpreted as ‘if $B$ then $H$’. $B$ and $H$ in turn can be a complex definition as well, constructed from conjunctions ($\wedge$), disjunctions ($\vee$), existential ($\exists$), or universal quantifiers ($\forall$).

We focus on reasoning on instance level (ABox), through definitions defined across the five ontology meta-structures. We differentiate between Inference and Restrictions definitions. The former are definitions that assign new classes or properties to a certain individual, e.g. $\exists$observes.$\text{TemperatureSensor}$ describes that an individual that observes the property Temperature can be inferred as a TemperatureSensor. In the Restriction case, the assignment of a certain class restricts the structure of the individual in terms of outgoing relations. For example, $\text{Observation} \subseteq \text{madeBySensorSensor}$ restricts the definition of Observations such that each individual that has assigned the Observation class can only be made by a Sensor. If a certain Observation would have been made by something that is not a Sensor, an inconsistency would be derived.

We identified four interesting reasoning perspectives, based on the position of L1 in the complex definitions, i.e. either in $B$ or $H$. With Other we denote all other levels, except L1. Table 6 summarizes the identified reasoning perspectives for each ontology.

**Perspective 1 ($L_1 \in B, Other \in H$):** concepts of L1 are present in $B$, while $H$ contains concepts outside of L1. This means that the event in the stream needs to be *enriched* with data outside of L1.

- **Inference:** inferences in this perspective imply that the events in the stream have an influence on the classification of the data defined outside of L1. None of the ontologies have predefined definitions in this perspective, except for object property domain and range definitions. For example, SAREF defines Device (L2) as the domain of the property makesMeasurement, which has Measurement (L1) as a range ($\exists$makesMeasurement.$T \subseteq \text{Device}$). We typically find definitions of this perspective in more specific application logic. For example, [24] defines application logic on top of SSN to define a FaultyTemperatureSensor (L2) is a Sensor (L2) that made an Observation (L1) which has a certain Symptom that is a TemperatureValueDeviation ($\exists$madeObservation.(Observation $\exists$hasSymptom. TemperatureValueDeviation) $\subseteq$ FaultyTemperatureSensor).

- **Restriction:** many ontologies define restrictions that span L1 into either L2 or L3. For example, SSN restricts an Observation (L1) as something that can only be made by a Sensor (L2). (Observation $\subseteq \text{madeBySensorSensor}$)

- **Optimization:** optimizing the Inference task is non-trivial as it requires to reclassify the more static data based on the content of the stream. The Restriction task is partly optimizable by materializing the more static data, such that the restrictions on the events in the streams can be computed by linking the event to the materialized static data and computing the consistency only of the instances defined in the event itself. This is similar to the idea of SubSet Reasoning [15] where a subset of the materialized data is extracted to reason upon the data in the stream.

**Perspective 2 ($L_1 \in H, Other \in B$):** concepts of L1 are defined in $H$, while $B$ contains concepts outside of L1. This also means that the event in the stream needs to be *enriched* with data outside of L1.

- **Inference:** None of the ontologies have definitions in this perspective, except for object property domain and range definitions. For example, SAREF defines Measurement (L1) as the domain of the property measurementMadeBy, which has Device (L2) as a range. However, we see that most of this perspective is defined directly in the application logic that builds on these ontologies. For example, the CityPulse project [50] defines ASP rules in this perspective, while [18] defines a CO2Observation as an Observation (L1) that is observed By a Sensor (L2) that observes the Property (L3) CO2. (Observation $\subseteq$madeBy.Sensor.CO2 $\subseteq$ CO2Observation)

- **Restriction:** Mostly the IoT ontologies define restrictions in this perspective. For example, SSN defines that a Sensor (L2) can only make

$^{15}$Both Symptom and TemperatureValueDeviation are application specific and not part of the SSN ontology.
observations of the type Observation (L1) (Sensor ⊑ \text{made}Observation, Observation).

- Optimization: the Inference tasks opens many opportunities for optimization as it allows to materialize the more static data and perform the reasoning on a restricted set of data around what is defined in the event [15] or try to cache the reasoning steps that are needed to reasoning on the event data [18].

Perspective 3 (Other ∈ H, Other \notin B): This perspective of definitions is defined solely on L1, allowing reasoning to be performed without any enrichment of the more static data in the other levels.

- Inference: None of the ontologies have definitions in this perspective, however, as an example, we could imagine an application extension of SIOC that defines AcademicPosts as Posts (L1) that describes a certain topic as the literal "academic".
- Restriction: Most of the IoT ontologies have again definitions in this perspective, e.g. SSN defines a Observation (L1) as something that only has instances of the type Results (L1) as result (Observation ⊑ \text{hasResult}Result).
- Optimization: This perspective allows to optimize as it does not require any interaction with the more static data defined outside of L1.

Perspective 4 (L1 \notin H, L1 \notin B): This perspective of definition are all defined outside of L1. Allowing the reasoning the be done independent of the content of the stream.

- Inference: Again none of the ontologies have predefined definitions in this perspective. However, we can again find examples in the application logic of certain projects. [25] defines a TemperatureSensor (L2) as a Sensor (L2) that observes the Property Temperature (L3) (Sensor ⊑ \text{observes}Temperature ⊑ TemperatureSensor).
- Restriction: Similar to Perspective 3, many of the IoT ontologies provide restrictions for this perspective. For example, SSN defines a Sensor (L2) as something that can only observe ObservableProperties (L3) (Sensor ⊑ \text{observes}ObservableProperty).
- Optimization: This perspective can be precomputed as reasoning can happen independent of the events in the stream.

Table 6

Various reasoning classes that influence an ontologies SR abilities. (R = Restriction, I = Inference, I_D = Domain/range inference).

So even though most ontologies were very expressive at first glance, they mainly use this expressivity to define restrictions on the various concepts, while the inference tasks are typically reserved for application specific logic.

6. Thousand Foot View: Streams’ Content

The Thousand Foot View of Streaming Linked Data focuses on the stream’s internals. In particular, we study the notion of Ontology Kernel (see Definition 5), and how the selected ontologies implement it. We reuse the ontologies introduced in the Ten-Thousand Foot View. Only eight of the ten selected ontologies describe concepts to represent the stream’s internals. These eight ontologies include SSN/SOSA, SAREF, IoTStream, SIOC, LODE, ActS, Frappe, and SAO/CES. The other ontologies are not included in this discussion.

RQ1c What characterizes the knowledge representation efforts for managing streaming heterogeneous data when the modeling efforts are limited to the event level?

6.1. Analysis Framework

The Common Event Model (CEM) was initially proposed by Westermann and Jain for multimedia applications [66], CEM is designed for historical event analytics. Thus, it does not relate to L4 and L5. When porting CEM to SR/RSP, we must reinterpret some aspects. Traditionally, data streams are characterized by a form of punctuation that allows streaming operators
to iterate over an unbounded sequence of data [61]. In SR/RSP, punctuation relates to the stream shapes, e.g., Graph, Triple, Predicate, as well as with the notion of Event Types [29]. At the ontological level, this reflects on the levels of conceptualization, especially L1. Thus, we introduce the following notion:

**Definition 5.** An **Ontology Kernel** is the minimal set of classes and properties of a certain ontology used to represent the instantaneous level.

In our analysis, we highlight the relation between the Kernel and the ontological layers presented in Section 5. Figure 7 visualizes the Kernel, highlighting CEM’s dimensions and the ontological levels. CEM describes events’ data according to the following dimensions:

**Informational:** the data and metadata that describe the event, e.g. the event type and other entities involved in the event.

**Experiential:** the data and metadata that link the event with the transporting media, e.g., images, sensor measurements, or audio snippets.

**Spatial:** data and metadata that describes where the event occurred. Spatial metadata are further organized in conceptual (e.g., a building), logical (e.g. an address), and physical (e.g. a UNIX timestamp) distinction applies. Moreover, CEM distinguishes between point-based and interval-based time semantics.

**Structural:** data and metadata about the event’s structure, e.g., how they are aggregated and linked to each other. As RDF is being used to model the event, we identify four event structures based on query shapes, i.e., Stars, Cycles, Chains, and Trees, as visualized in Figure 8. Note that ontologies allow to model events using multiple shapes.

**Composition:** Allows the event model to compose the events into a larger whole, e.g. a smoke and high temperature observation observed in the same room could be composed into a fire observation. We do not consider the composition or aggregation of events at the event modeling level, as SR allows to define compositions or aggregations at higher levels of abstraction [57].

**Causal:** data and metadata that describe what caused the event and how. Notably, causality is a form of provenance that in SR is typically described at query level. Coherently with the assumption to leave processing as future work, we do not include it in the analysis.

6.2. Discussion

We now align each of the ontologies with the CEM. We distinguish the Informational and Experiential discussion over the two levels L1 and L2. The higher the level, the further away from the core. L1 is one property link away from the core, e.g. a type assertion and linked entities, while L2 requires two hops, e.g. types of the linked entities of L2 or additional entities) We provide a summary of the analysis for the Informational and Experiential discussion in Table 7 and for the Spatial and Temporal discussion in Table 8.

**Informational.** On L1, the ontologies describe the types of the events. For the sensor ontologies (SSN, SOSA, and IoTStream) the types of the events are `sosa:Observations`, with the extension of `iots:StreamObservation` for IoTStream. These ontologies are very generic, it is the responsibility of the user to further specify the `Observation` types, e.g. to add specific `Observations` such as a `TemperatureObservation` to the ontology. SAREF describes `srfr:Measurements` instead of `sosa:Observations` and already provides a number of specific types in a form of a hierarchy. Both SSN and SAREF specify a number of ontological restrictions that can be enforced by the reasoners, e.g. each `sosa:Observation` should be made by exactly one `sosa:Sensor`. SOSA is more lightweight.
as it does not contain any restrictions. SIOC describes `sioc:Item` and `sioc:Post` as the event types, a shallow hierarchy, and no type restrictions are defined. In LODE, `lode:Event` is the central event type, no event hierarchies or type restrictions are included. `as:Activities` represent the main types in the ActS ontology. It defines a hierarchy of `as:Activities` and a small number of restrictions for some activity subtypes. Frappe imports `eo:Event` from the Event Ontology as event types with neither hierarchies nor restrictions. We see that L1 Informational type definitions are mostly very simple, except for SSN and SAREF. SSN has its lightweight version SOSA to make the modeling of the events more simple. The fact that the event description is rather simple in ontological complexity is in line with the Cascading Reasoning principle in SR that states that high-velocity streams should be processed with simple processing techniques, while once the streams have been filtered, more advanced processing can be performed using more expressive reasoning techniques [17]. Next to the event Types, L1 also links to the Entities that are involved in the event.

On L2, informational data include the types of the L1 linked Entities which describe the Static level of the ontology. In particular, the IoT ontologies (SSN, SOSA, IoTStream, and SAO) link the `sos:Observation` to `sos:Sensors` that made the observations and `sos:ObservableProperties`
that have been observed. IotStream has the additional iots:IotStream concept that iots:
StreamObservations can belong to, while SAO links to the specific sao:Stream Analysis that
was executed to extract the iots:IotStream from the sosa:Observations. SAREF links its
srf:Measurements to srf:Devices (instead of Sensors) and the observed Properties. In SIOC, on
an Informational L2, sioc:Items and sioc:Posts are linked to the involved sioc:Users or sioc:
UserGroups. In LODE, the lode:Events are linked to the involved lode:Objects and lode:
Actors in a very generic way. as:Activities in ActS can be linked on an Informational L2 to the
involved as:Objects and as:Links. In Frappe, the eo:Events are linked to frp:Places they are
happening in. The ontological complexity of L2 is in line with L1, i.e., SSN and SAREF define restrictions,
while SAREF, SIOC, and ActS define hierarchies of concepts.

Note that many of the classes of Informational L1 align with the Instantaneous level of the Ten-Thousand
Foot View even though these are two different ways of looking at the classes of the ontologies. In the previous,
view we looked at the classes that had a temporal annotation, while in this view we look at the
classes used for modeling the events. They align as the events themselves are what change over time.

Experiential. On L1, experiential data are the event payload. The sensor ontologies (SSN, SOSA, IoT-
Stream, SAO, and SAREF) describe sensor values. SIOC describes the post content and ActS describes the
name, summary, and content (as HTML) of the activity. Frappe and LODE do not support experiential
properties. On L2, experiential data are the static entities’ metadata. SAREF allows its srf:Devices to have properties that can uniquely characterize it, namely its model and manufacturer. In SIOC
sioc:Users and sioc:UserGroups can maintain metadata about their size, while users can have
a name and avatar. In ActS, as:Objects can have all sorts of metadata such as name, content, and summary. All other ontologies do not support experiential L2 properties out of the box.

Temporal. SSN/SOSA defines two temporal concepts, i.e. sosa:resultTime and sosa:phenomenonTime. The data property sosa:resultTime has xsd:dateTime as range and provides point-
semantics. The object property sosa:phenomenonTime is more expressive and allows to model both in-
terval and point semantics through the use of time:
TemporalEntity. In IotStream, the class iots:
StreamObservation defines the interval of the window it belongs to using the data properties iots:
windowStart and iots:windowEnd (with range xsd:dateTimeStamp). SAO allows the use of the TimeLine Ontology for both interval and point semantics for the extracted sosa:StreamEvents.
In SAREF, srf:Measurements can have point-
semantics using the data property srf:hasTime-
stamp (with range xsd:dateTime), while srf:
Properties can have both point and interval semantics using the object property srf:hasTime (with range time:TemporalEntity). In SIOC, sioc:Posts can be annotated using point-semantics using dcterms:created and dcterms:modified with a literal using ISO-8601 formatted date values. In LODE, the lode:Events can be time-
stamped both with point as interval semantics with the lode:atTime object property with time:Temporal-
Entity as domain that can model both point and interval semantics. In ActS, interval-based time semantics are supported using data properties as:start-
Time and as:endTime (with xsd:dateTime as range). In Frappe, eo:Events have point-based
timeInterval semantics using the property frp:time with time:Instant as range.

Interestingly, we see that most ontology models rely on xsd:dateTime for point-semantics, while for interval-semantics, there does not seem to be a consensus. Some vocabularies chose to model their own intervals, e.g. start & end Time, while others rely on time:TemporalEntity.

Spatial. For the spatial definition, we make a distinction between physical, conceptual, and logical definitions. SSN, SOSA, and SAREF have no out-of-the-box support for spatial definitions. In IotStream, the iots:IotStreams have physical locations defined through geo:location (with geo:Point as range). SOA allows modeling the location of Features of Interest that are being observed using geo: Spatial Thing. In SIOC, logical locations are supported, i.e. sioc:Sites can be the location of an online community and a sioc:Space is defined as being a place where data resides. In LODE, lode:Events can have conceptual locations using lode:atPlace (with dulf:Place as range) or physical locations using lode:inSpace (with geo: Spatial Thing as a range). In ActS, as:Activities can have both physical and logical definitions through the definition of the as:Place.
Ontology | Spatial | Temporal
--- | --- | ---
SSN | No support | Point (xsd:dateTime);
SOSA | Same as SSN | Interval (time:TemporalEntity)
IoT Stream | Physical locations (geo:Point), | Same as SSN
| | | Self defined Interval (xsd:dateTimeStamp)
SAREF core | No support | Point (xsd:dateTime)
SIOC | Logical | Interval (time:TemporalEntity)
LODE | Conceptual (dul:Place) | Point
| | Physical (geo: SpatialThing) | Interval (time:TemporalEntity)
ActS | Physical (lode:Place) | Self defined Interval (xsd:dateTime)
| Logical (lode:Place) | |
Frappe | Physical (geosparql: SpatialObject) | Point-semantics (time:Instant);
| Conceptual (geosparql: SpatialObject) | Self defined Interval (xsd:dateTime).
SAO | Physical (geo: SpatialThing) | Same as SSN+
| Conceptual (geo: SpatialThing) | Point and Interval (TimeLine Ontology)

Object. In Frappe, `eo: Events` can have both physical and conceptual locations defined through location (with `frp: Place` as range, which is a subclass of `geosparql: SpatialObject`). Note that `geosparql: SpatialObject` can define both physical and conceptual locations. We saw that physical spatial definitions typically rely on the `geo` and `geosparql` imported ontologies, while conceptual locations on `DUL` and `geosparql`.

Structural. Figure 9 shows an example of the SOSA ontology, where both Chain, Stars, Cycles, and Trees can be used. However, we saw in the literature that the Star is most often used. The same holds for SSN, IoTStream, and SAREF. Other ontologies model both Chain, Stars, and Trees. However, the Star seems to be the best suited for streaming purposes. Indeed, when going up in ontology structure levels (e.g. Informational L2) data becomes more static, and as the event itself is typically kept limited in size, the more static data is not described in the event itself but linked through informational L1 (Entities). Chains are not particularly useful as they only allow to move from the core of the kernel to the outer level through Informational Entity relations. At the end of the chain, there can optionally be only Informational Type or Experiential data, as these data end the chain. Cycles share the same faith, as they only allow to cycle through Informational Entity relations, without any Experiential or Type data, as these data end the cycle. Trees can model all data, but tend to describe unnecessary static data. Stars can model Informational L1, both the type of the event itself and the linked Entities, while describing the data in the Experiential L1, making it ideal for event modeling. Table 9 and 10 summarize the analysis.

Understanding the structure of the events is important as it opens many opportunities for optimizations, as
it allows to clarify how a query can optimally interact with the events. For example, Stars could be represented as a table (instead of an RDF graph) allowing part of the querying to be offloaded to lower-level processing techniques that operate before the conversion to RDF which can improve performance [10]. Fernandez et al. [32] showed that identifying regularities in the structure of the data in the stream allows to improve transmission by structure-tailored compression techniques. Furthermore, Bonte et al. [14] showed that understanding the structure of the events in the stream allows to optimize the continuous query evaluation process. These kinds of optimizations then on their own can lead to better modeling guidelines for SLD ontologies.

Composition. Most ontologies allow some sort of composition through logical reasoning between the kernel and data that is modeled outside of the kernel, as discussed in Section 5.3. However, it is worth noting that some ontologies allow to define compositions that go beyond traditional logical reasoning. SOA/CES allows to define temporal patterns through the Complex Event Processing (CEP) definitions supported by the CES ontology. These CEP definitions allow defining the composition of various events that have a temporal dependency. Frappe allows compositions by defining aggregations on the captured data through statistical inference. Similarly, IoTStream allows to define how different Analytics have been computed on the data stream that also allows some sort of statistical inference to perform composition over various events. SAO has similar functionality through its StreamAnalysis concept, and even predefines a number of analyses, among others KMeans, MovingAverage and DiscreteCosineTransform.

7. Best Practices for Streaming Linked Data

We now discuss a number of Best Practices (BP), extracted from our analysis, that can improve the modeling efforts of Streaming Linked Data.

BP1 When modeling an ontology, aim to maximize FAIR coverage.

BP2 When a single ontology is not aligned with the FAIR principles, aim to combine ontologies in order to maximize FAIR coverage.

BP3 Aim for ontologies that have a clear differentiation regarding their meta-structure, as identifying the change frequency of instances based on their assigned concepts allows to optimize the processing.

BP4 Keep the reasoning expressivity of the concepts that define the event as low as possible.

BP5 Avoid Reasoning Perspective 1 in which the event data influence the classification of the more static data, as it is not trivial to optimize.

BP6 Check the expressivity of the imported ontologies and try to limit the imported expressivity.

BP7 Keep the kernel as small as possible.

BP8 Rely on an event structure that can easily be translated to a more simple representation, such as the Star.

BP9 When modeling temporal information, regardless of the need for point or time semantics, use widely accepted existing temporal concepts such as time:TemporalEntity in order to maintain uniformity and improve interoperability.

BP10 Similarly for spatial information, refrain from introducing custom location-specific concepts and reuse concepts from the geo or geosparql ontologies.
8. Related Work

Dell’Aglio et al. [29] recently surveyed the state-of-the-art of stream reasoning research. They initially identified 9 requirements for a stream reasoning system to satisfy, then they analyzed the compliance of existing works to them. Although the authors discuss streaming annotation, which is comparable to our Thirty-Thousand Foot View, they do not explicitly compare ontologies themselves.

Margarà et al. [45] also surveyed solutions for stream reasoning and RDF stream processing. The focus of this survey was on comparing system capabilities and identifying limitations in terms of RDF stream processing. Although related to potential future work, we did not include processing in this current work. Thus, this survey can be seen as complementary.

In the context of the Semantic Web for the Internet of Things, the work of Szilagy et al. [55] is related. The authors discuss the advantages of semantic annotation for solving interoperability issues in the IoT domain. Then, they propose a specialized version of the Semantic Web stack for IoT. Although Szilagy et al. propose to compare four ontologies, including SSN, the comparison is not the main focus of their work. Moreover, the analysis’s scope is limited to IoT and does not include ontologies like SIOC and LODE.

Finally, Gyrard et al. [34] describe a Linked Open Vocabulary (LOV) for IoT projects (LOV4IoT). LOV4IoT identified existing IoT ontologies, re-engineered the vocabularies to make them interoperable, and cataloged them. However, they did not investigate each of the ontologies’ capabilities for modeling data streams and LOV4IoT is limited to IoT applications.

9. Conclusion

In this paper, we surveyed the work on KR for Streaming Linked Data. In particular, we presented 1) a Thirty-Thousand Foot View observing streams as Web resources, 2) a Ten-Thousand Foot View that observes the nature and nurture of the ontologies for streaming data starting from a bottom-up approach, and 3) a Thousand Foot View, which zooms further in and discusses how different ontologies model the events in the stream. Our analysis can be summarized as follows:

From thirty-thousand foot, most Stream description ontologies do not completely adhere to the FAIR principle. However, a combination of VoCALS and SAO/IoTStream fulfills most of the requirements. From Ten-thousand foot, ontologies distributed their complexity alongside five time-related dimensions, i.e., Instantaneous (L1), Static (L2), Time Agnostic (L3), Time-varying (L4), and Continuous (L5). The L4 is where most differences can be spotted. Most interestingly, ontologies explicitly designed for Streaming Linked Data ignore L3 and elaborate on L5. Finally, from a thousand foot we noticed that a little semantic goes a long way. Ontologies keep their kernel small under the assumption that the further away from the kernel, the more static the data. Additionally, while there is no consensus on how time is represented, a star-shaped event is the most prominent one.

As not all ontologies cover all aspects and different views, to be compliant with the Streaming Linked Data principles, a combination of SR ontologies is recommended.

As future work, we plan to extend the analysis to include a Five-Hundred Foot View and a Hundred Foot View that respectively observe how (RDF) streams are serialized (data formats) and served (protocols). Furthermore, we aim to zoom in further on the processing part, i.e., L5 of the Ten-Thousand Foot View and the Causal dimension of the Thousand Foot View.

Our analysis introduced a number of reasoning perspectives, which opens opportunities to design an ontology profile that opens the possibilities for various reasoning optimization that can be identified by the different perspectives. Our analysis frameworks also open various directions in terms of optimized processing. For example, the Ten-Thousand-Foot View opens optimizations by explicitly defining the interaction between the data in the stream (instantaneous level) and more slowly changing data. Similarly, the Thousand Foot View opens optimizations by identifying the different shapes of events. In terms of knowledge representation, we have identified opportunities to define ontology metrics for SLD ontologies, starting from our analysis frameworks.

Most importantly, our analysis frameworks can aid to evaluate future ontologies for Streaming Linked Data and serve as a guideline for high-quality knowledge representation.
